PACIFIC GAS AND ELECTRIC COMPANY
ELECTRICAL UNDERGROUNDING PLAN
ATTACHMENT A
PROGRESS REPORT 0 NARRATIVE

A. Introduction

Pacific Gas and Electric Company (PG&E) submits this Progress Report consistent with Section 2.6.1 of the Electrical Undergrounding Plan (EUP) Guidelines.

Progress Report 0 requires PG&E to include narratives that are also required to be included in the EUP. Accordingly, for ease of review, PG&E's Progress Report 0 includes references to the applicable chapters and sections of the EUP to direct the reader to the relevant sections of the EUP where the required narrative content is addressed in lieu of providing a duplicative narrative. This approach reflects that Progress Report 0 is based on information available at the time of submission of the EUP and is intended to establish baseline reporting consistency with the approved EUP.

For future Progress Reports, PG&E will provide an updated narrative for any sections that have changed since the prior report, including updates to assumptions, methodologies, data inputs, or implementation status, consistent with the reporting requirements of the EUP as discussed in chapter 6 of the EUP.

B. Progress Report Required Content (EUP Guidelines Section 2.6.1)

Progress Report 0 must be based on information and data available at the time of submission. The Circuit Segment Information Lists, including the Confirmed Projects List and the Prioritized Project List, submitted in Progress Report 0 must meet the minimum requirements described in Section 2.4.1 for Screen 3.

Progress Report 0 must, at a minimum, include the following sections:

a. Portfolio Coversheet (narrative);
b. Example Rejected Project(s) (see Section 2.4.5.2, Twenty Five Undergrounding Project Requirement);
c. Plan Mitigation Objective (narrative);
d. Plan Tracking Objectives (narrative);
e. Target/Timeline Table (narrative);
f. Identified Wildfire Rebuild Areas (narrative);
g. Model Report (see Section 2.7.2);
h. Alternative Mitigation Selection Process (narrative);

i. All data required pursuant to Section 2.8 and Appendix C of these Guidelines; and

j. Any additional System Level, Portfolio Level and Project Level information the Large Electrical Corporation would like to be included in Progress Reports.

1. Progress Report Organization

Our Progress Report is organized as set forth in Table A-1 below.

TABLE A-1
EUP GUIDELINES REQUIREMENTS

Line No.	EUP Guidelines Section	EUP Guidelines Requirement	Requirement Reference in Progress Report
1	2.8.6.1	Portfolio Coversheet	Attachment A-1
2	2.4.5.2	Example Rejected Project	Section 1 b
3	2.3.1	Plan Mitigation Objective	Section 1 c
4	2.3.2	Plan Tracking Objectives	Section 1 d
5	2.5.1	Target/Timeline Table	Section 1 e
6	2.4.3.1	Identified Wildfire Rebuild Areas	Section 1 f
7	2.7.2	Model Report	Section 1 g
8	2.4.4	Alternative Mitigations Selection Process	Section 1 h
9	2.8 & Appendix C	Required Data	Section 1 i
10	2.4.4.1	SPD-37 Appendix 1 Required Data	Section 1 j

a. Portfolio Coversheet

See EUP Chapter 9 and Attachment A-1: Portfolio Coversheet.

b. Example Rejected Project(s)

See EUP Chapter 3, Section 3.D.3.b, for a description of a Rejected Project.

c. Plan Mitigation Objective

See EUP Chapter 2, Section D for a description of the Plan Mitigation Objective.

d. Plan Tracking Objectives

See EUP Chapter 2, Section E for a description of the Plan Tracking Objectives. The Plan Tracking Objectives Table 2-13 as included in Chapter 2 will be updated in each Progress Report.

e. Target/Timeline Table

See EUP Chapter 2, Section D.10 for information about the Target/Timeline Table. The Target/Timeline Table is also included below as Table A-2 and will be updated in each Progress Report.

TABLE A-2
TARGET/TIMELINE TABLE

10	10	1/1/2037 - 12/31/2037	625	500	5,000	0	$3.56	$2.90	15.7	803	77.6	5,877
11	End Total	12/31/2037	5,000	4,000	5,000	0			$208	$11,768	$453	$30,953

(a) Underground mileage is estimated by applying a 1.25 multiplier to the corresponding overhead mileage deenergized. The 2028 undergrounding mileage shown in the EUP Target/Timeline Table (250 miles) differs from the mileage approved in the 2026 WMP (400 miles). The difference is primarily due to the time needed to transition the program and its supporting structure to meet the EUP requirements. Once the EUP is approved, PG&E will update the WMP mileage at the appropriate time.

(b) Pre-construction miles are calculated as the sum of undergrounding miles required to be in the planning process in the next two years that are needed to meet execution targets. These miles reflect the number of miles passing Screen 3 and Screen 4. There is a two year lead time for pre construction miles (e.g., 650 miles in 2028 is the sum of planned miles for 2029 and 2030).

(c) To establish 2028 unit cost values, 2025 actual costs are escalated to 2028 dollars. The “Unit Cost Escalated” column reflects annual unit cost values further escalated from 2028 dollars to the dollar value in the applicable year (2028–2037). The “Unit Cost Unescalated” column reflects annual unit cost values presented in unescalated 2028 dollars and incorporates assumed unit cost reductions over time as program efficiencies are realized. Cost assumptions applied in the current WBCA model for Screen 2 are based on average 2028 unit costs; however, costs for individual projects may vary based on project-specific feasibility multipliers.

(d) Instantaneous and cumulative risk values represent unmitigated Wildfire and Outage Program Risk for all years prior to project completion, and post-mitigated risk from the year the project is completed onward. PG&E applies the Risk Model Impact Factor, climate escalation, and inflation adjustments as described in this section.

(e) Totals may not exactly equal the sum of individual values because figures are rounded independently.

f. Identified Wildfire Rebuild Areas

See EUP Chapter 3, Section D.1.a for information regarding the process used to Identify Circuit Segments in Fire Rebuild Areas. A list of wildfires and Fire Rebuild Areas is attached as Table C.24.

g. Model Report

See Chapter 7, Section D, for information on these sections of the Model Report Chapters:

- Ignition Likelihood Model;
- Ignition Consequence Model;
- Outage Program Risk Model: EPSS;
- Outage Program Risk Model: PSPS;
- Overall Utility Risk Model;
- Wildfire Benefit Cost Analysis Model; and
- Enterprise Risk Bow Tie.

h. Alternative Mitigation Selection Process

See EUP Chapter 3, Section D.2, for information on the mitigation selection process.

i. Required Data: EUP Guidelines Section 2.8 and Appendix C

Data required by EUP Guidelines Section 2.7.7, 2.8.6.1, 2.8.6.2, and 2.8.6.3 is included in the Portfolio Coversheet (Attachment A-1) as directed in EUP Guidelines Section 2.8.6.4.

The data required by EUP Guidelines Appendix C is attached to this Progress Report as Attachments A-2 to A-5. PG&E's assumptions and limitations regarding the submitted data are outlined in the following sections of EUP Chapter 6:

- Tabular Data Submission – Section C.1.b;
- JSON Data Submission – Section C.1.c; and
- Spatial Data Submission – Section C.1.d.

j. CPUC SPD-37, Appendix 1: SB 884 Project List Tables

The CPUC data required in Resolution SPD-37, Appendix 1, as updated by the CPUC Safety Policy Division in its *SB 884 Project List Data Requirements Guidelines* dated May 11, 2026, is attached to the EUP as Attachment D and will be included in subsequent Progress

Reports. The SPD-37 data is described in EUP Chapter 3, Section D.2.a.1.

C. Data Submitted With Progress Report 0

Table A-3 below lists attachments, tables, and data files included with Progress Report 0.

PORTFOLIO COVERSHEET

A. Summary

The Portfolio Coversheet is organized as follows, as required by EUP Guidelines Section 2.8.6.4:

TABLE PCS-1:
EUP GUIDELINES REQUIREMENTS ADDRESSED IN PORTFOLIO COVERSHEET

Line No.	EUP Guidelines Section	EUP Guidelines Requirement	Requirement Reference in Portfolio Coversheet
1	2.8.6.1	Narrative Justification	Section B
2	2.8.6.2	Key Decision-Making Metrics Profiles	Section C
3	2.7.7	Project Variable Modifiers	Section D
4	2.8.6.3	Portfolio Development	Section E

B. Narrative Justification (EUP Guidelines Section 2.8.6.1)

The Portfolio Coversheet is a text document which summarizes the macro-level impacts of the EUP. The Large Electrical Corporation must submit the Portfolio Coversheet in Progress Report 0 and each subsequent Progress Report. The content of the Portfolio Coversheet must be updated with the most up-to-date information available in each Progress Report.

The figures and tables in the Portfolio Coversheet will summarize the most important aspects of the risk modeling at the System-Level and Portfolio-Level, and must be accompanied by a data submission as detailed in Appendix C.

The Portfolio Coversheet must include a narrative section which details the formal definition and calculations of the Portfolio-Level Standards as directed in Section 2.7.8 of these Guidelines.

The Portfolio Coversheet must include a narrative of no more than one page explaining why any Circuit Segment in the top 5 percent of Overall Utility Risk by score was not included in the EUP.

The Portfolio Coversheet must include a table showing the instantaneous and cumulative values or scores for each Key Decision Making Metrics (KDMM) at 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 25, 30, 35, 40, 45, 50, and 55 years. The instantaneous values describe the risk at a single moment in time, while the cumulative values indicate the accumulation over a time. Values that do not accumulate over time, such as consequence scores, must be reported as a value at a given time.

The Portfolio Coversheet summarizes the macro-level impacts of the EUP in compliance with Sections 2.8.6.1 to 2.8.6.4 of the EUP Guidelines. This Portfolio Coversheet summarizes the Plan Mitigation Objective, KDMM, and Project Variable Modifiers (PVM) that demonstrate where undergrounding achieves superior risk-reduction performance relative to Alternative Mitigations. The figures and tables in the Portfolio Coversheet follow Energy Safety's Guidelines and will summarize the most important aspects of the risk modeling at the System-Level and Portfolio-Level. The data required in Appendix C will be provided with the Progress Report.

Future Portfolio Coversheets will maintain this structure while updating Wildfire Distribution Risk Model, version 4 (WDRM v4) and KDMM outputs to reflect current conditions and measured progress toward the Plan Mitigation Objective.

1. Macro-Level Impacts

Implementing our EUP will significantly reduce ignition and reliability risk in the High Fire Threat District (HFTD). Implementation of the EUP is expected to reduce Overall Utility Risk by approximately $3 million per mile of overhead miles removed over the 55-year life of undergrounding assets within the HFTD. This assumes that we harden approximately 4,000 miles of overhead distribution lines by moving them underground. Additional overhead lines will be removed through overhead covered conductor installation and line removal with remote grid; this work will be funded primarily through PG&E's General Rate Cases.

2. Portfolio-Level Standards

PG&E's Portfolio Standards are discussed in EUP Chapter 7, Section L. Table PCS-2 below details PG&E's Risk Decrease Standards and Reliability Increase Standards. PG&E will update Table PCS-2 to show our progress towards the Portfolio Level Standards in each Portfolio Coversheet. Portfolio 0, as reflected in Progress Report 0, meets both the Portfolio Level Ignition Decrease Standard and the Portfolio Level Reliability Increase Standard. However, neither of the System Level Standards are currently being met. The System Level metrics are normalized across total system miles, therefore, as the portfolio expands, the gap to meeting the System

Level Standards is expected to decrease. Table PCS-2 below details PG&E's Risk Decrease Standards and Reliability Increase Standards as well as the progress towards achieving these standards.

TABLE PCS-2
PORTFOLIO STANDARDS

Line No.	Standard	Value	Portfolio 0
1	Ignition Risk Decrease Standard at Portfolio Level	$0.147M/mile	$0.263M/mile
2	Reliability Increase Standard at Portfolio Level	$0.211M/mile	$0.266M/mile
3	Ignition Risk Decrease Standard at System Level	$0.007M/mile	$0.0004M/mile
4	Reliability Increase Standard at System Level	$0.010M/mile	$0.0004M/mile

3. Exclusion of Circuit Segments in Top 5 Percent of Overall Utility Risk

Excluded Circuit Segments in the top 5 percent of Overall Utility Risk, when identified, will be listed in Table PCS-3. To date, no Circuit Segments have been excluded from the Portfolio. (See EUP Chapter 9, Section E.3.)

TABLE PCS-3
EXCLUDED CIRCUIT SEGMENTS

Line No.	Circuit Segment ID	Reason for Exclusion
1	[To be added]	[To be added]
2	[To be added]	[To be added]

4. Instantaneous and Cumulative Risk Scores for Each KDMM

The KDMMs are non-financial measures a utility uses to measure how effective an Undergrounding Project will be at reducing wildfire risk. They reflect real-world, observable risk conditions and are not shaped by financial factors or risk preferences. These metrics can be applied at three scales—systemwide, across a portfolio of Circuit Segments, or for a single Project—to show how much risk is concentrated or reduced at each level. PG&E's KDMMs are discussed in PG&E's EUP Chapter 7, Section E.

Tables PCS-4 and PCS-5 show the instantaneous risk scores and cumulative risk scores for each KDMM, which demonstrates how much Ignition Risk, Outage Program Risk, and Overall Utility Risk is expected to

decrease as the Portfolio is constructed. All numbers are shown in 2028 dollars. Tables PCS-4 and PCS-5 will be updated as the EUP progresses.

TABLE PCS-4
INSTANTANEOUS RISK SCORES FOR EACH KDMM

			Ignition			Outage

20	55	$40.921	$40.921	0.083	$492.776	$0.000	0.000	$0.076

Note: These values currently reflect Projects slated for 2028 in the UG workplan. As additional Progress Reports are issued, the table will be updated to account for the additional Projects (i.e., the 2028 Year 0 will not change as there will not be additional Projects for 2028; however, Year 1 will see an increase in all the values as the Projects for 2029 finish with scoping their values will get populated for Years 1 onwards).

C. System and Portfolio-Level Risk Matrices and Profiles for Key Decision-Making Metrics (EUP Guidelines Section 2.8.6.2)

The EUP must include a series of visualizations and tables for each of the KDMMs showing the KDMM's distribution both with and without the Portfolio's modeled mitigation. These visualizations will be included in the Portfolio Coversheet.

On the Portfolio Coversheet, each KDMM's distribution must be reported on both a system wide and Portfolio-wide scale and emphasize the position of projects within the Risk Landscape. Every figure and table on the Portfolio Coversheet must include a caption explaining the figure.

Risk scores, the product of likelihood and consequence, must be reported as two dimensional risk matrices. Risk scores can be weighted if appropriate. Two examples of risk score matrices for Ignition Risk are presented below (Figures 3-6), followed by another example of a risk score matrix for Outage Program Risk (Figures 7-10).

The Portfolio, illustrated in Figures PCS-3 to PCS-12 below, is based on high-level cost and scope assumptions consistent with Screen 2 requirements. The Undergrounding Projects in this Portfolio are subject to change as assumptions are refined through the detailed risk evaluation in Screen 3 and represent an approximation of pre- and post-mitigated KDMMs based on available information.

The primary goal of the KDMM figures below is to demonstrate that likelihood decreases following mitigation actions. This reduction is evident in the high risk, tail risk, and high frequency outage program Circuit Segment points. Post-mitigation likelihood for each Circuit Segment is calculated as:

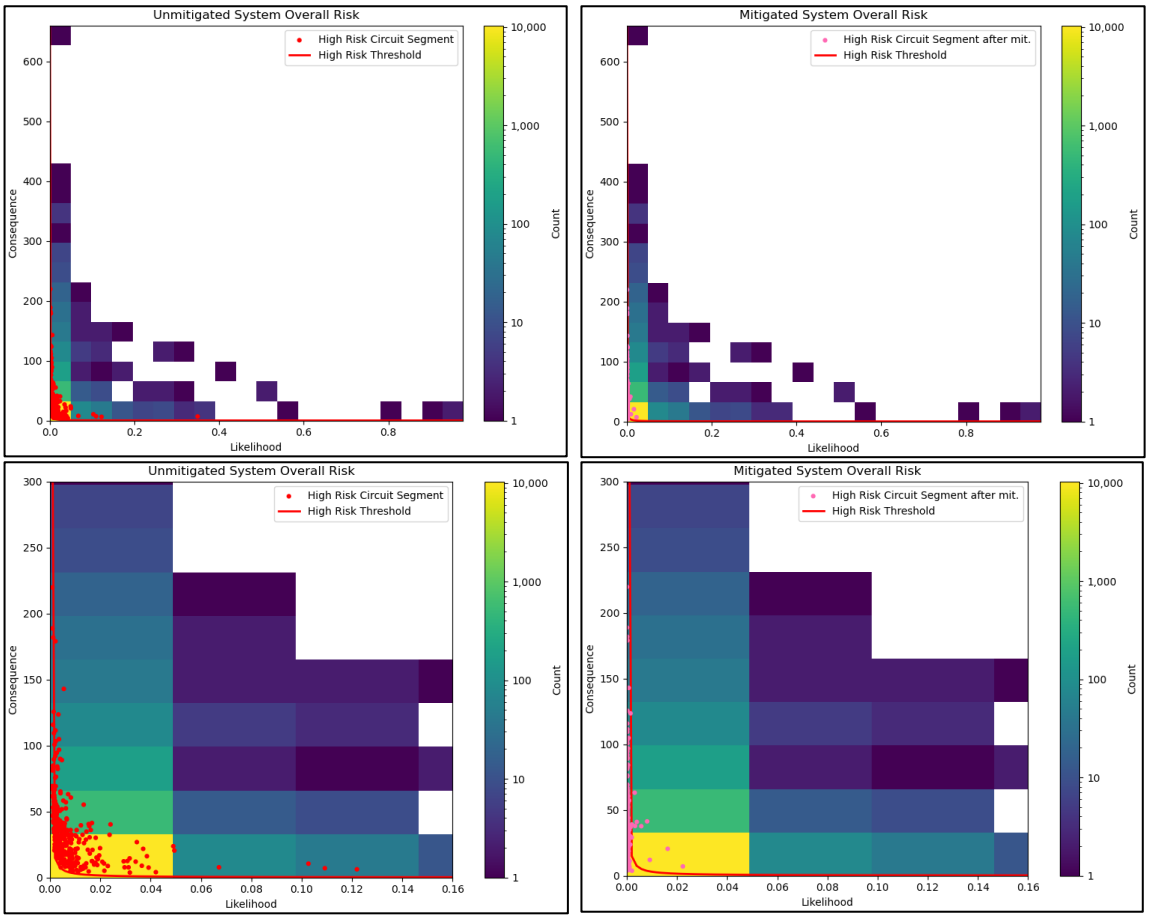

$$\textbf{Formula}: Mitigation\ Liklehood = Unmitigated\ Likelihood * (1 - Effective\ Mitigation\ Fraction)$$

The Effective Mitigation Fraction represents the proportion of HFTD/HFRA overhead line mileage within the Circuit Segment that is treated, weighted by the mitigation-effectiveness of each treatment type, including undergrounding and overhead hardening. Circuit Segments that receive undergrounding and/or overhead hardening are assigned proportional mitigation credit based on the fraction of treated mileage relative to the total HFTD/HFRA overhead mileage within that segment. Consequence is assumed to remain unchanged by mitigation, with only likelihood being reduced.

1. Overall Utility Risk (System)

Figure PCS-3 below (based on EUP Example Figure 3) demonstrates the substantial improvement in Overall Utility Risk expected from the EUP, using Overall Utility Risk as a KDMM. Each figure plots Adverse Event Consequence on the y-axis (arbitrary units) against Adverse Event Likelihood on the x-axis (arbitrary units), incorporating both Outage Program Risk and Ignition Risk. Due to the Outage Program Risk and Ignition Risk using fundamentally different likelihood scales (outage-minutes/year vs ignitions/year), neither likelihood nor consequence can be expressed in a single standard unit. To produce a unified visual, we normalize each component likelihood to a 0-1 scale, then compute a risk-weighted average that reflects each component's share of total segment risk. Consequence is back-calculated via Consequence = Risk / Likelihood. Likelihood and Consequence are provided per mile, to allow project risk to be ranked without being skewed by high risk/high mileage Projects. While the individual axes do not carry direct physical units, the relative positioning of segments represents their comparative risk profiles, and the underlying dollar-denominated risk values are preserved in the product of the two axes. The background heatmap represents the modeled distribution of Circuit Segments across the system. The red diagonal line represents the High-Risk Threshold used to identify candidate segments for undergrounding. All figures in this Portfolio Coversheet are also in EUP Chapter 9.

FIGURE PCS-3:
RISK SCORE MATRIX DEMONSTRATING SUBSTANTIAL IMPROVEMENTS IN OVERALL UTILITY RISK EXPECTED DUE TO EUP

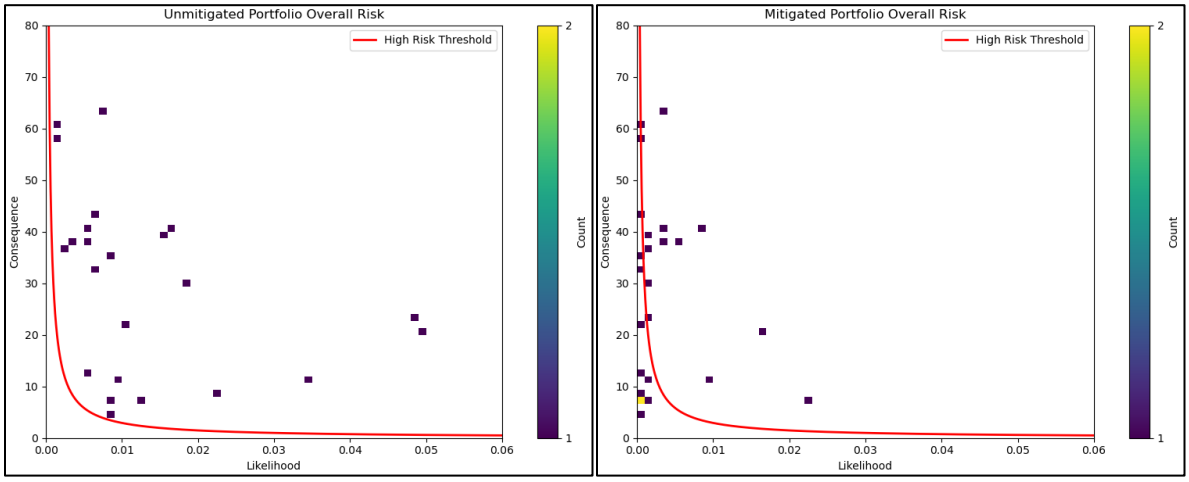

- Left (upper): Modeled system conditions prior to implementation of EUP mitigations. Red points represent Circuit Segments selected for undergrounding because they exceed the High-Risk Threshold.
- Right (upper): Modeled system conditions after undergrounding is applied to the selected segments. The heatmap reflects the modeled reduction in likelihood associated with undergrounding. Pink points represent the same selected Circuit Segments after mitigation.
- Left (lower): Zoomed view of pre-mitigation conditions, focused on high- risk Circuit Segments to highlight their position above the High-Risk Threshold.
- Right (lower): Zoomed view of post-mitigation conditions for the same Circuit Segments, illustrating their transition after mitigation relative to the High-Risk Threshold.

2. Overall Utility Risk (Portfolio)

Figure PCS-4 below (based on EUP Example Figure 4) displays only the EUP Project portfolio, rather than the entire system Overall Utility Risk.

FIGURE PCS-4
RISK SCORE MATRIX FOR PORTFOLIO LEVEL OVERALL UTILITY RISK

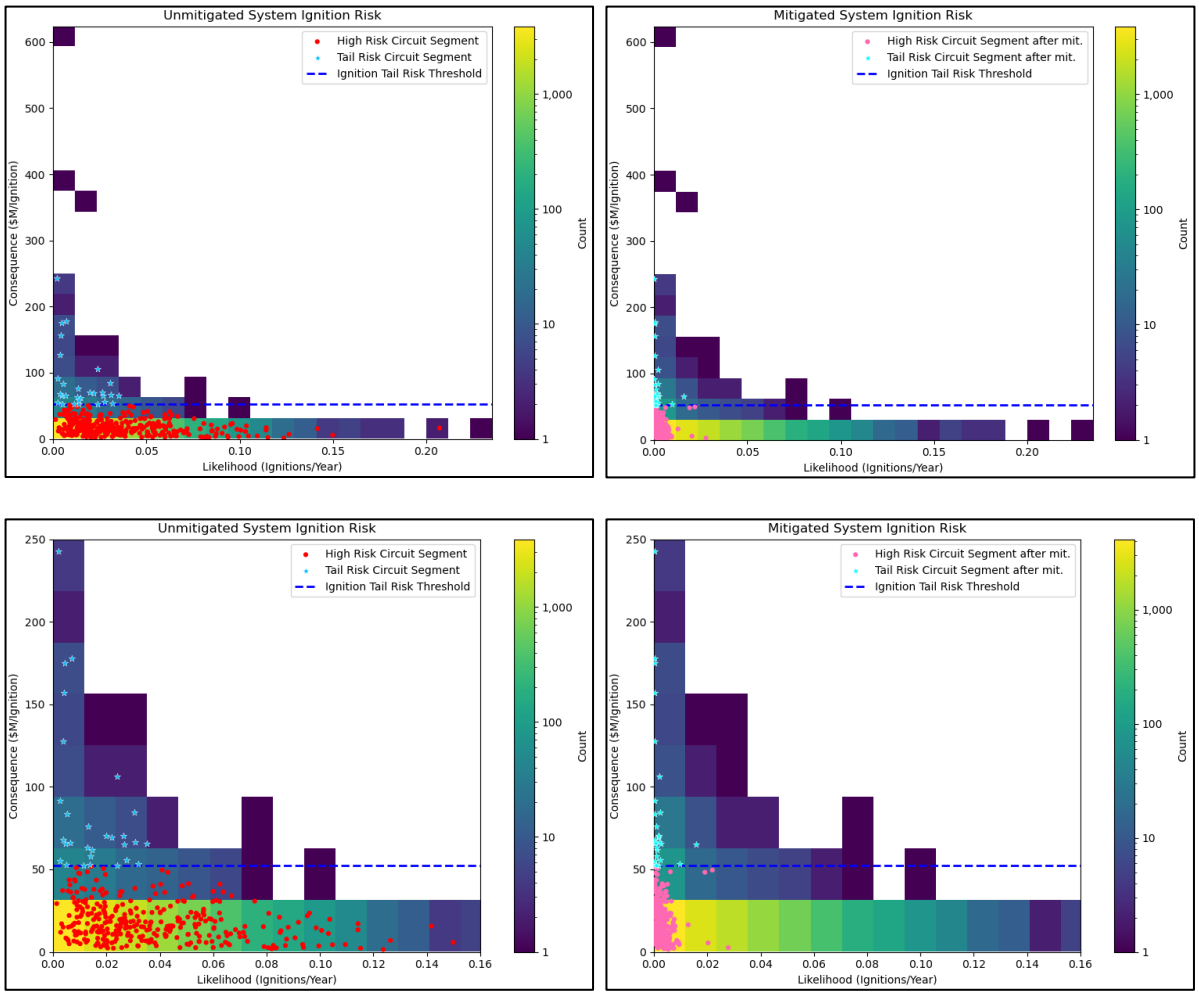

- Left: Portfolio risk distribution prior to mitigation.
- Right: Portfolio risk distribution after undergrounding mitigations are applied.

3. Ignition Risk (System)

Figure PCS-5 below (based on EUP Example Figure 5) demonstrates the substantial improvement in Ignition Risk expected due to the EUP. Each figure plots Ignition Consequence on the y-axis (arbitrary units) and Ignition Likelihood on the x-axis (arbitrary units). The background heatmap shows the modeled system distribution, with the Ignition Tail Risk Threshold shown as a blue dotted line.

FIGURE PCS-5
RISK SCORE DEMONSTRATION OF SUBSTANTIAL IMPROVEMENTS IN IGNITION RISK

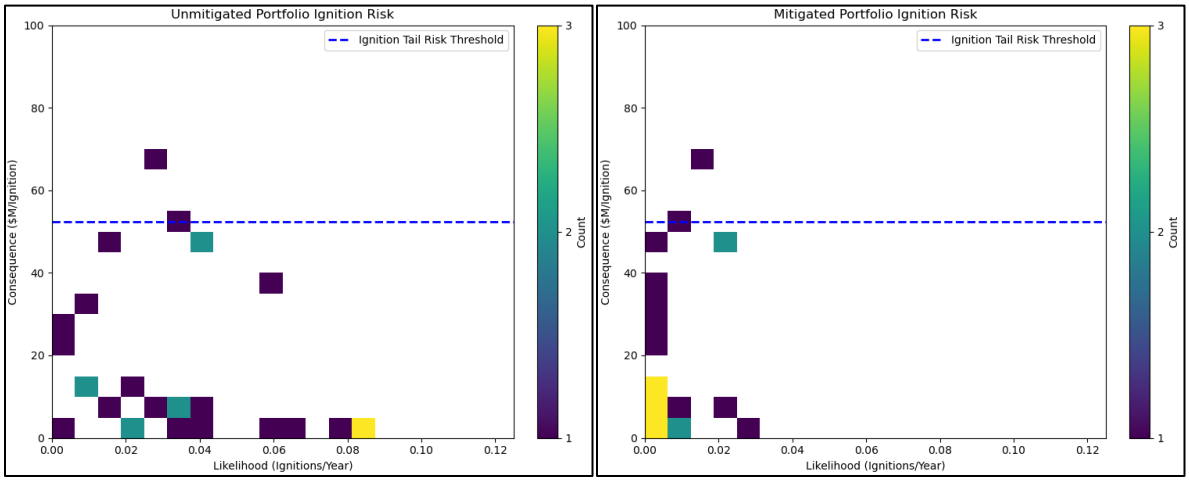

- Left (upper): Modeled system conditions prior to EUP mitigations. Red points represent Circuit Segments selected for undergrounding based on exceeding the High-Risk Threshold. Blue stars represent Circuit Segments selected for exceeding the Ignition Tail Risk Threshold.

- Right (upper): Modeled system conditions after undergrounding. The heatmap reflects reduced likelihood for mitigated segments. Pink points and teal stars represent the same High-Risk and Tail Risk Circuit Segments, respectively, after mitigation.
- Left (lower): Zoomed view of pre-mitigation conditions, focused on High-Risk and Tail Risk Circuit Segments to highlight their position relative to the Ignition Tail Risk Threshold.
- Right (lower): Zoomed view of post-mitigation conditions for the same Circuit Segments, illustrating their transition after mitigation relative to the Ignition Tail Risk Threshold.

4. Ignition Risk (Portfolio)

Figure PCS-6 below (based on EUP Example Figure 6) displays the EUP Portfolio risk rather than the full system risk.

FIGURE PCS-6
RISK SCORE MATRIX FOR PORTFOLIO LEVEL IGNITION RISK

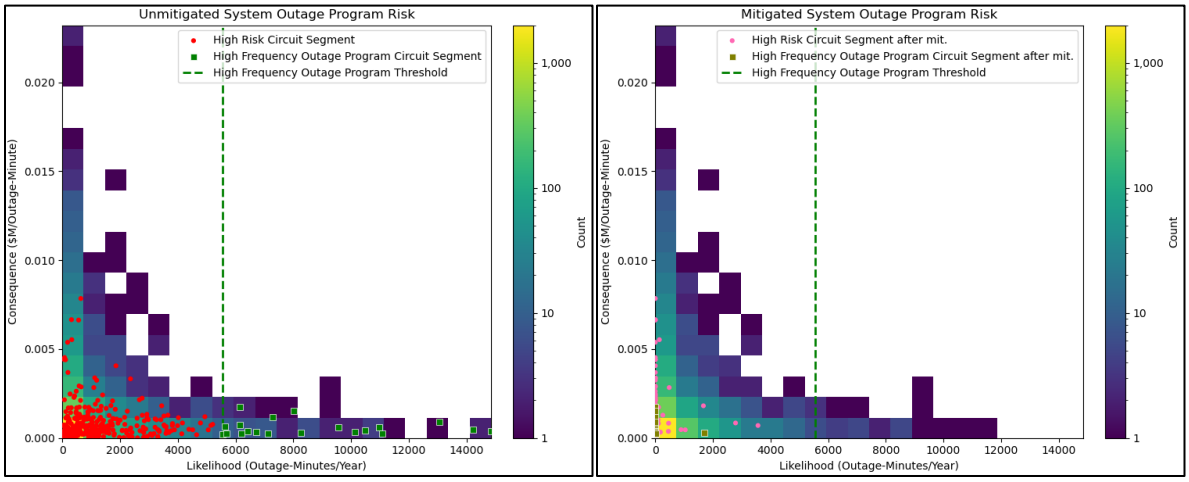

- Left: Portfolio risk distribution prior to mitigation.
- Right: Portfolio risk distribution after mitigation.

5. Outage Program Risk (System)

Figure PCS-7 below (based on EUP Example Figure 7) demonstrates the substantial improvement in Outage Program Risk expected from the EUP. Each figure plots Outage Program Consequence on the y-axis (arbitrary units) and Outage Program Likelihood on the x-axis (arbitrary units). The background heatmap represents the modeled system distribution. The High-Frequency Outage Program Threshold is shown as a green dotted line.

FIGURE PCS-7
RISK SCORE MATRIX FOR DEMONSTRATION OF SUBSTANTIAL IMPROVEMENT IN OUTAGE PROGRAM RISK

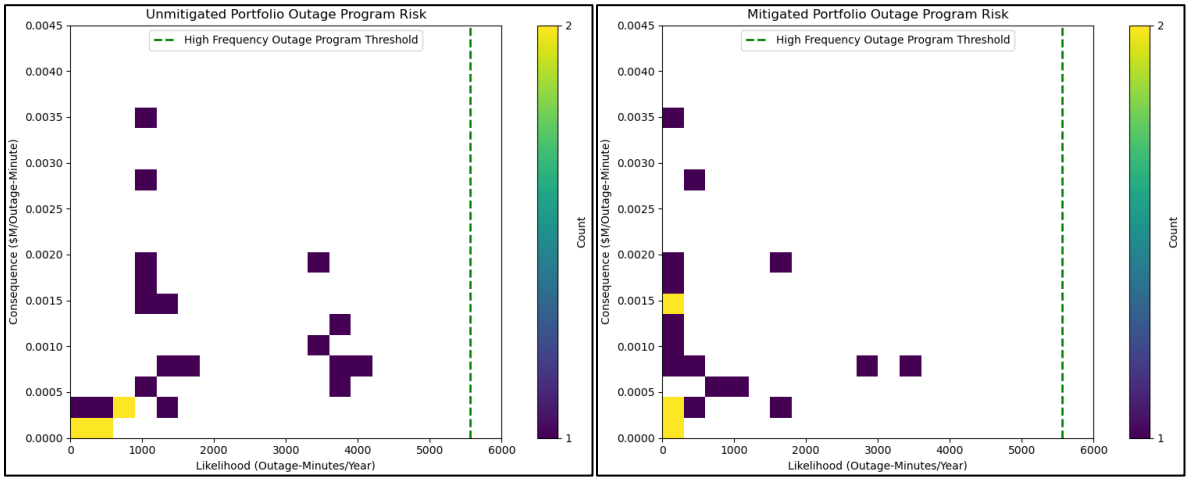

- Left: Modeled system conditions prior to EUP mitigations. Red points represent Circuit Segments selected for undergrounding due to exceeding the High Risk Threshold. Green squares represent Circuit Segments exceeding the High-Frequency Outage Program Threshold.
- Right: Modeled system conditions after undergrounding. The heatmap reflects reduced likelihood. Pink points and olive squares represent the same High-Risk and High-Frequency Outage Circuit Segments, respectively, after mitigation. The post-mitigation Circuit Segment points are tightly clustered near zero, making them difficult to distinguish individually in the visualization.

6. Outage Program Risk (Portfolio)

Figure PCS-8 below (based on EUP Example Figure 8) displays only the EUP Project portfolio.

FIGURE PCS-8
RISK MATRIX FOR PORTFOLIO-LEVEL OUTAGE PROGRAM RISK

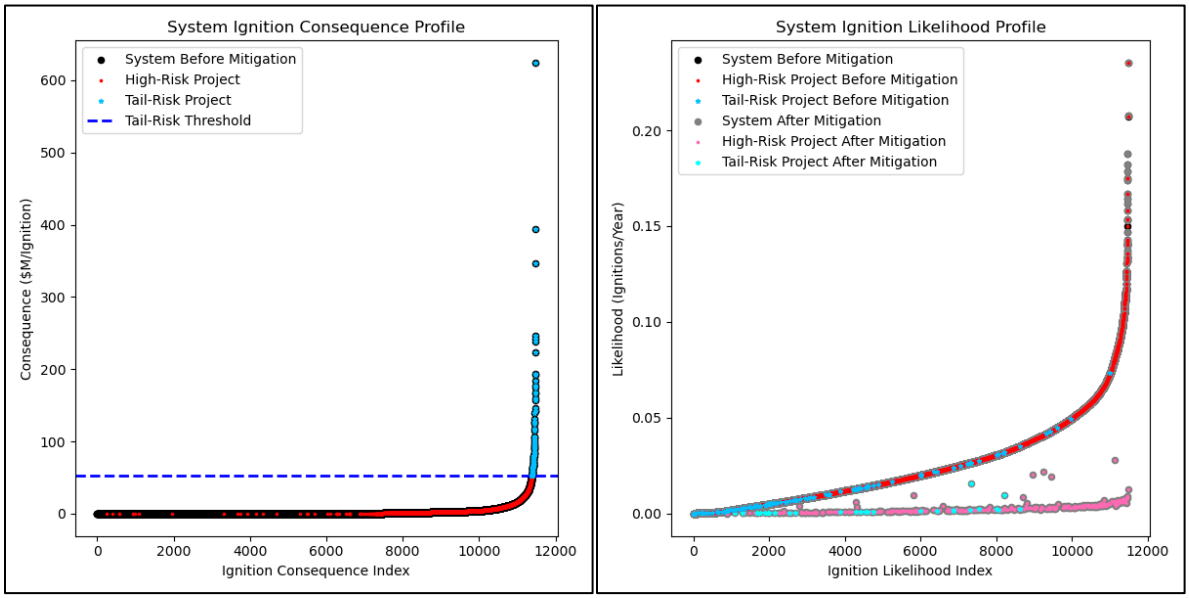

- Left: Portfolio risk distribution prior to mitigation.
- Right: Portfolio risk distribution after mitigation.

7. Ignition Consequence and Likelihood (System)

Figure PCS-9 below (based on EUP Example Figure 9) presents Ignition Consequence and Ignition Likelihood profiles for Circuit Segments selected using Ignition Risk and wildfire consequence as KDMMs.

FIGURE PCS-9
IGNITION CONSEQUENCE AND LIKELIHOOD PROFILES

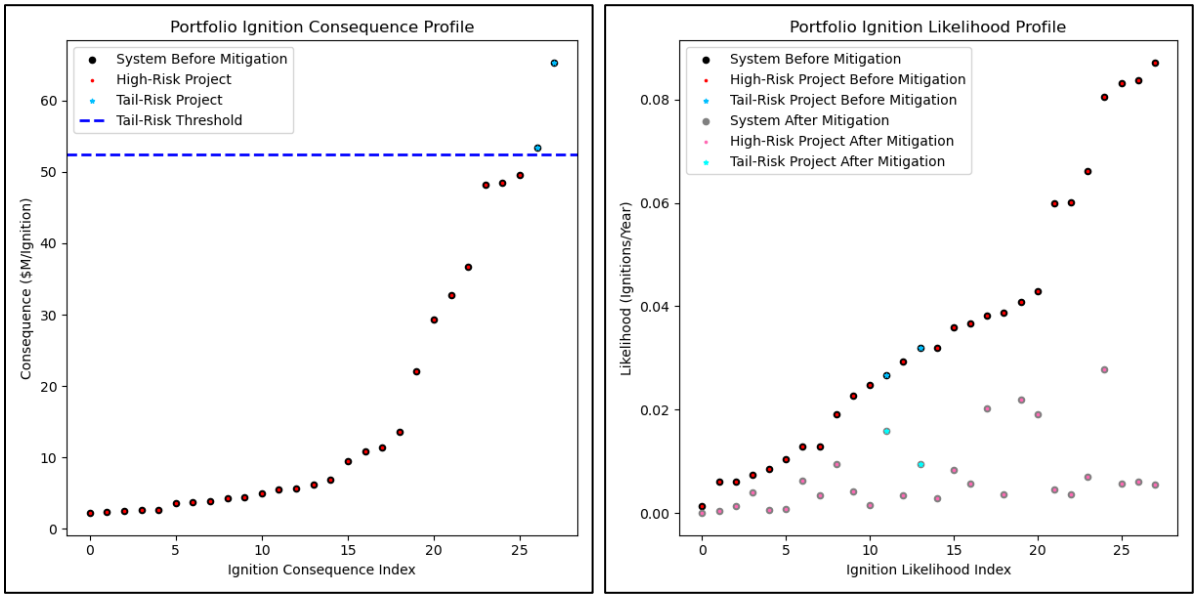

- Left: All Circuit Segments ordered from lowest to highest Ignition Consequence, with consequence scores shown on the y-axis (arbitrary units). The blue line represents the Ignition Tail Risk Threshold. Blue stars indicate Circuit Segments exceeding this threshold. Red dots represent high risk Circuit Segments selected based on overall Ignition Risk. Since undergrounding affects likelihood, but not consequence, this panel is unchanged by mitigation.
- Right: All Circuit Segments ordered from lowest to highest Ignition Likelihood. Red points and blue stars correspond to the same Circuit Segments shown in the left panel. Grey points show the modeled system after mitigation, with pink points and cyan stars representing undergrounded high risk and tail risk Circuit Segments, respectively.

8. Ignition Consequence and Likelihood (Portfolio)

Figure PCS-10 below presents Ignition Consequence and Ignition Likelihood profiles for Circuit Segments in the EUP Portfolio.

FIGURE PCS-10
PORTFOLIO IGNITION CONSEQUENCE AND LIKELIHOOD PROFILES

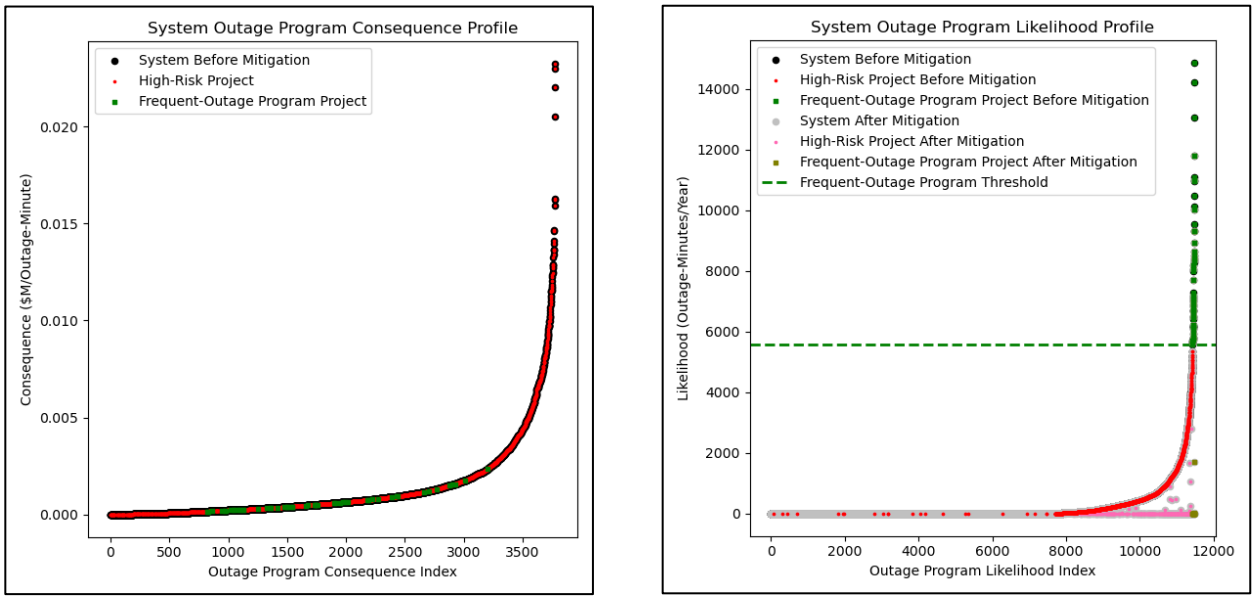

- Left: Portfolio Ignition Consequence.
- Right: Portfolio Ignition Likelihood.

9. Outage Program Consequence and Likelihood (System)

Figure PCS-11 below (based on Example Figure 10) presents Outage Program Consequence and Likelihood profiles for Circuit Segments selected using Outage Program Risk and Outage Program Consequence as KDMMs.

FIGURE PCS-11
OUTAGE PROGRAM CONSEQUENCE AND LIKELIHOOD PROFILES

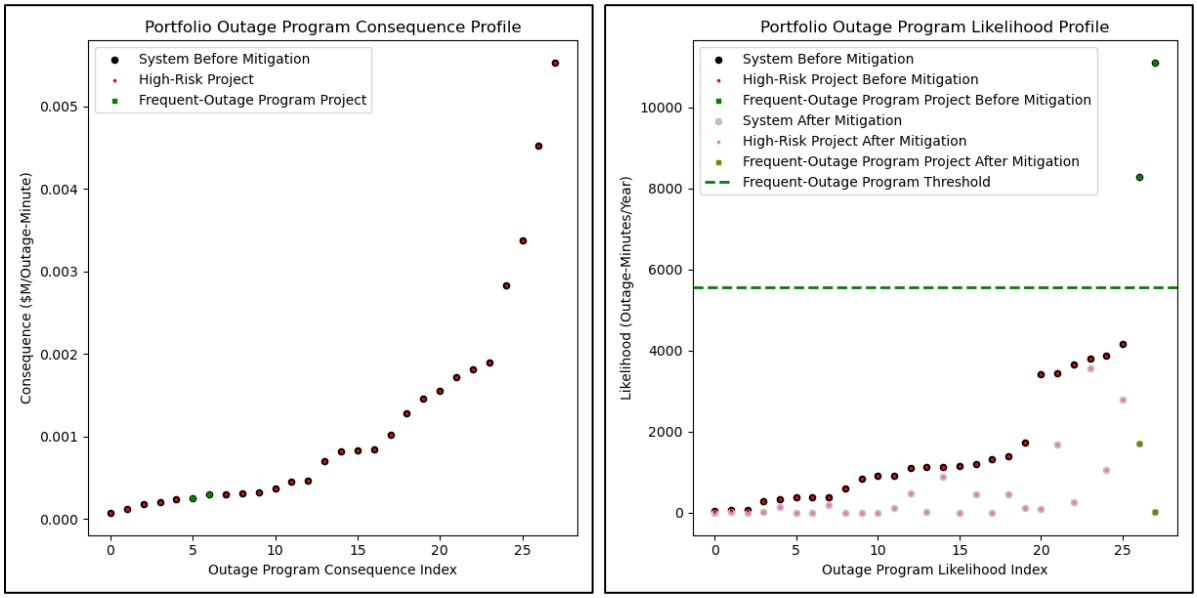

- Left: All Circuit Segments ordered from lowest to highest Outage Program Consequence, with consequence scores shown on the y-axis (arbitrary units). Green squares indicate Circuit Segments selected for undergrounding because their Outage Program Likelihood exceeds the High-Frequency Outage Program Threshold. Red dots represent high risk Circuit Segments selected based on overall Outage Program Risk. Since undergrounding affects likelihood, but not consequence, this panel is unchanged by mitigation.
- Right: All Circuit Segments ordered from lowest to highest Outage Program Likelihood. The green line represents the High-Frequency Outage Program Threshold. Green squares indicate pre-mitigation exceedances, and olive squares represent the same segments after mitigation. Grey points show the modeled system after mitigation, with pink points and olive stars highlighting undergrounded high risk and high-frequency outage Circuit Segments.

10. Outage Program Consequence and Likelihood (Portfolio)

Figure PCS-12 below presents Ignition Consequence and Ignition Likelihood profiles for Circuit Segments in the EUP Portfolio.

FIGURE PCS-12:
PORTFOLIO OUTAGE PROGRAM CONSEQUENCE AND LIKELIHOOD PROFILES

- Left: Portfolio Outage Program Consequence.
- Right: Portfolio Outage Program Likelihood.

D. Project Variable Modifiers (EUP Guidelines Section 2.7.7)

A Project Variable Modifier is defined as a set of changes that are made to variables in the Risk Modeling Methodology to evaluate the effectiveness of a given project or set of projects and represents how the Large Electrical Corporation values the efficacy of the Alternative Mitigations. The Large Electrical Corporation must list each Project Variable Modifier, explain how the specific PVM was calculated, and explain if and how the use of a specific PVM varies in different evaluations of the Model Risk Landscape. Specifically, the Large Electrical Corporation should provide a general description summarizing what input variables to what calculations are changed, and what is the effect on the output variables and KDMMs. This information may be reported on an average-case basis.

The Large Electrical Corporation must provide a high-level description of the formal numerical processes used to arrive at the PVM. If the Large Electrical Corporation employs third-party studies to get to the PVM, it must cite the studies here. If the PVM is the result of internal studies, then the Large Electrical Corporation must describe the datasets, and detail the formal calculations. The Large Electrical Corporation must also make the third-party studies and data available to Energy Safety upon request, both during the review of the EUP and anytime during the expected lifetime of the assets installed through the EUP.

PG&E uses PVMs to adjust certain inputs in risk models to demonstrate how individual Undergrounding Projects or groups of Projects reduce wildfire-related risk. (See PG&E's EUP Chapter 7, Section K for details of the PVM methodology.) The following section introduces these PVMs and their mitigation effectiveness.

1. Reporting PVMs (EUP Guidelines Section 2.8.5.2)

The EUP and each Progress Report (including Progress Report 0) must contain a table summarizing the PVMs as referenced in Section 2.7 and Section 2.8.6 of these Guidelines.

The "Mitigation Type" column describes the nature of the work conducted in the project. The Large Electrical Corporation must, at minimum, consider the Alternative Mitigations described in Section 2.7.10. It may include other alternative methods or divide these types of projects into differentiable sub types when appropriate.

The "Model" column indicates which models the PVM effects.

The "Inputs Modified" column describes which of the model inputs are changed.

The "Delta" column describes how the inputs are changed, and may be represented as percentages, changes in distribution, changes in category or any other changes to the inputs that the PVM accomplishes.

The "Other Notes" column contains narrative material that clarifies the way that the PVM affects the inputs.

The Large Electrical Corporation must report the effects of applying these PVMs to its Portfolio. The Large Electrical Corporation must compute the distribution of the changes to each KDMM for each mitigation type and report it in a table that will be attached to the Portfolio Coversheet.

PG&E defines PVMs as the values used in the WBCA to determine the effectiveness of an Alternative Mitigation at the sub-driver level. Table PCS-6 of the Portfolio Coversheet summarizes the PVM Inputs referenced in Sections 2.7 and 2.8.6 of the EUP Guidelines. Table PCS-6 captures Other Notes, which point to the relevant Workpapers that describe the sub-drivers to each input. Please refer to WP001 for a detailed description of the methodology used to calculate mitigation effectiveness values as shown in the Delta column.

Table PCS-7 includes PVM Outputs. In Table PCS-7, the "Change" column reflects the adjustment to the KDMM values resulting from the application of the mitigation relative to the baseline value. This metric is measured on a systemwide basis. The permanent system hardening mitigation alternatives evaluated in the EUP are modeled as reducing ignition likelihood only. Consequence values remain unchanged for these mitigations because they are driven by underlying factors such as terrain, weather, population exposure, etc. and are therefore represented as N/A. The "Variance" column reflects the variability in mitigation effectiveness across Circuit Segments relative to the systemwide average change shown in the "Change" column. For example, for OH, the systemwide change in Overall Utility Risk is -38%. However, at the Circuit Segment level, individual segment impacts may vary, ranging from -38% to +27%, relative to the systemwide average.

For each mitigation type, PG&E will report in the Portfolio Coversheet the changes to each KDMM resulting from the application of the PVMs. PG&E will update these results when Risk Model calibrations are made that materially affect PVM inputs, assumptions, or estimated mitigation effectiveness. See Chapter 7, Section K for additional information on PVMs and Chapter 8 for the Risk Model versioning and calibration schedule.

(a) The “Change” column reflects the adjustment to the KDMM values resulting from the application of the mitigation relative to the baseline value. This metric is measured on a systemwide basis. The permanent system hardening mitigation alternatives evaluated in the EUP are modeled as reducing ignition likelihood only. Consequence values remain unchanged for these mitigations because they are driven by underlying factors such as terrain, weather, population exposure, etc. and are therefore represented as N/A.

(b) The “Variance” column reflects the variability in mitigation effectiveness across Circuit Segments relative to the systemwide average change shown in the “Change” column.

E. Portfolio Development (EUP Guidelines Section 2.8.6.3)

The Large Electrical Corporation must detail its system for tracking changes in the Portfolio of Undergrounding Projects over time as well as the consistency of its modeling updates.

The Large Electrical Corporation must track how its Portfolio of Undergrounding Projects has changed over the duration of the EUP by applying the most up-to-date modeling system version and calibration to each of the historical Portfolios considered during the lifetime of the EUP.

The Large Electrical Corporation must summarize this information in each Progress Report, including Progress Report 0, by creating two plots for each KDMM showing their mean value and first standard variation, measured over the total Portfolio footprint. The total Portfolio footprint is defined as the union of all Circuit Segments included in any Portfolio.

The first plot must show the instantaneous value of the KDMM after the EUP has been completed, as measured by the most recent version and calibration of Risk Modeling Methodology, compared to the Baseline at the beginning of the plan, as measured by the most recent version of the Risk Modeling Methodology.

The second plot must show the same metrics but measured by the version of the Risk Modeling Methodology that was most recent at the time the Portfolio was updated.

1. Tracking Changes in the Portfolio of Undergrounding Projects

We will show how the Portfolio changes over the life of the EUP by creating two plots for each KDMM, showing their mean value and first standard variation, measured over the Portfolio.

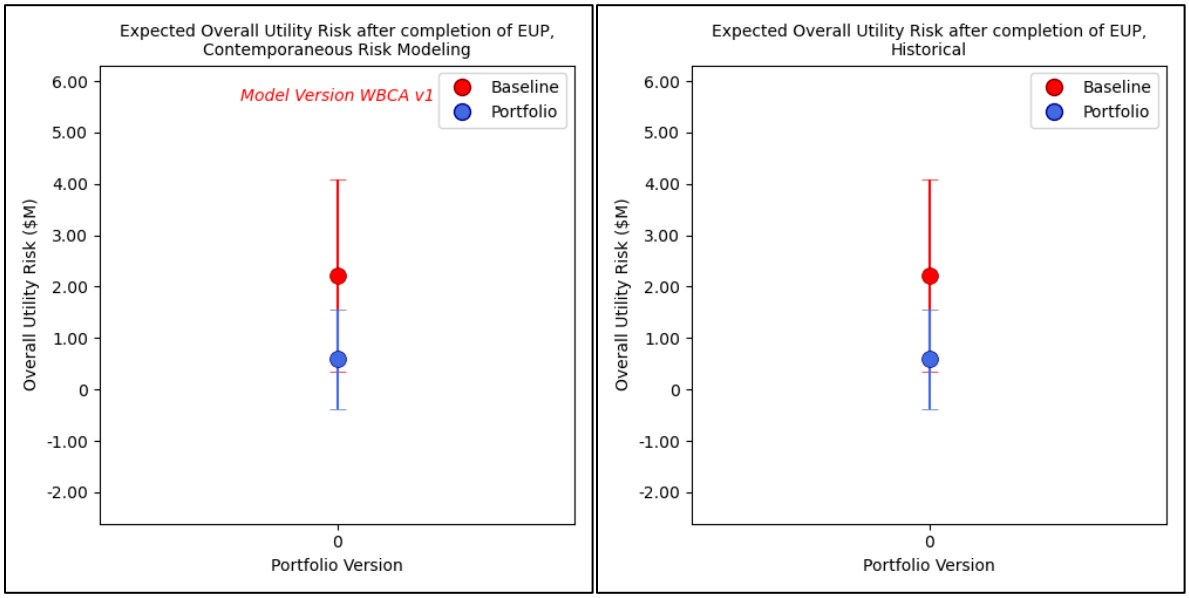

Figures PCS-13A through PCS-13E below present KDMM plots showing the mean value and first standard deviation, measured over the total Portfolio. This information will be updated and included in each subsequent Progress Report. Note that, due to EUP Guideline requirements for the figures below, the distributions are skewed; therefore, the mean and standard deviation are not representative of the distribution's center and spread.

Because Progress Report 0 is the initial report, only a single data point is represented in the figures below. As subsequent Progress Reports are filed, and additional data is plotted over time, the changes to the Portfolio of Undergrounding Projects will be observable.

a. Overall Utility Risk

Figure PCS-13A will illustrate the reductions in Overall Utility Risk as we implement Portfolio 0.

FIGURE PCS-13A
KDMM DEVELOPMENT: CHANGES IN PORTFOLIO OVERALL UTILITY RISK

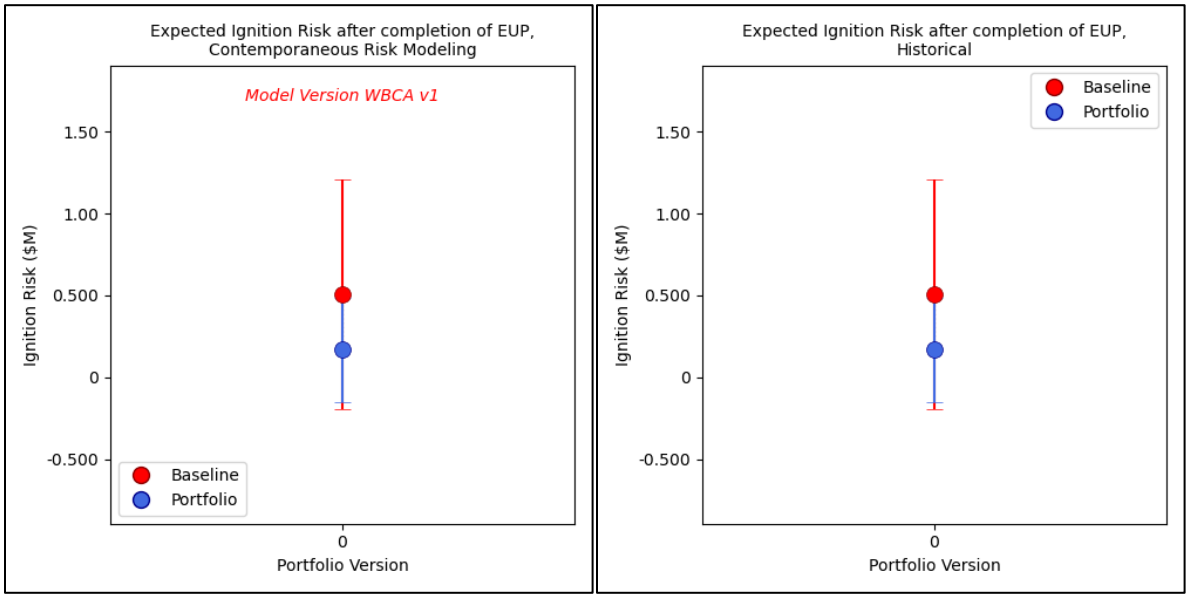

- Left: A plot showing the mean and standard deviation of the Overall Utility Risk's Baseline (red) and modeled value after EUP mitigation (blue) of Circuit Segments in the Portfolio, using the most recent version of the model, WBCA v1. The x-axis denotes the version of the Portfolio. Note that due to the skew of the risk distribution, mean and standard deviation are not representative of the center and spread of the distribution.
- Right: A plot showing the mean and standard deviation of the Overall Utility Risk's Baseline (red) and modeled value after EUP mitigation (blue) of Circuit Segments in the Portfolio, using the WBCA v1, which was most recent at the time the Portfolio was updated. Note that due to the skew of the risk distribution, mean and standard deviation are not representative of the center and spread of the distribution.

b. Ignition Risk

Figure PCS-13B will demonstrate reductions to system Ignition Risk following implementation of the EUP Portfolio 0.

FIGURE PCS-13B
KDMM DEVELOPMENT: CHANGES IN PORTFOLIO IGNITION RISK

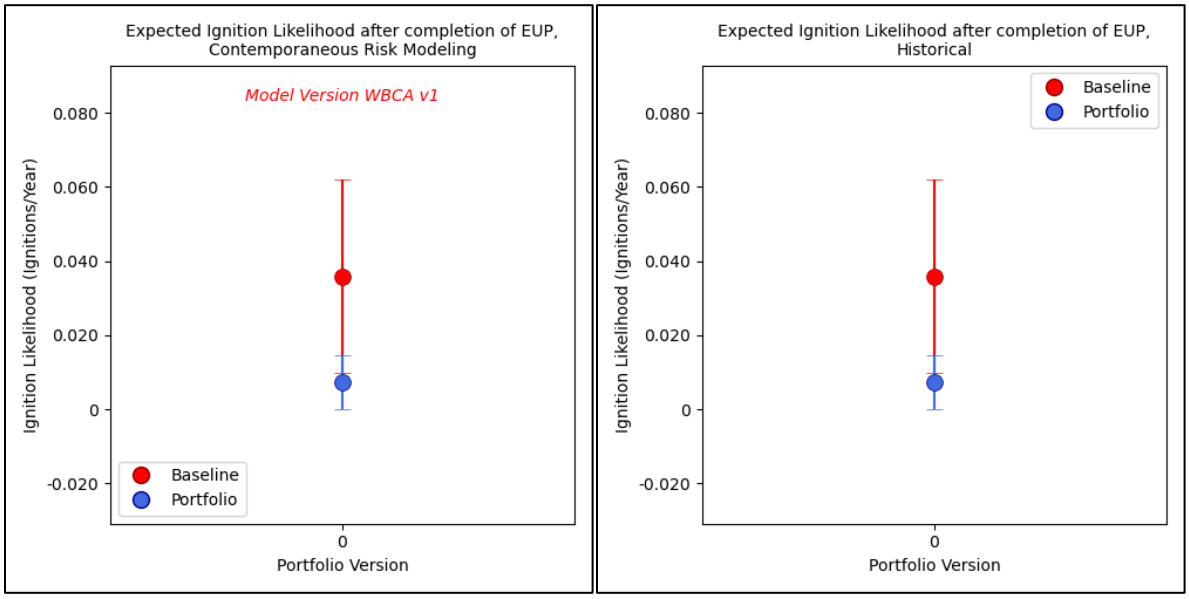

- Left: A plot showing the mean and standard deviation of the Ignition Risk's Baseline (red) and modeled value after EUP mitigation (blue) of Circuit Segments in the Portfolio, using the most recent version of the model, WBCA v1. The x-axis denotes a different version of the Portfolio.
- Right: A plot showing the mean and standard deviation of the Ignition Risk's Baseline (red) and modeled value after EUP mitigation (blue) of Circuit Segments in the Portfolio, using the WBCA v1, which was most recent at the time the Portfolio was updated.

c. Ignition Consequence and Likelihood

KDMM graphs are not produced for Ignition Consequence, as EUP mitigation minimally modifies the consequence of an ignition, thus the modeled value after EUP mitigation is unchanged.

Figure PCS-13C will indicate that the system's Ignition Likelihood declines with the implementation of the EUP Portfolio 0.

FIGURE PCS-13C
CHANGES IN PORTFOLIO IGNITION LIKELIHOOD

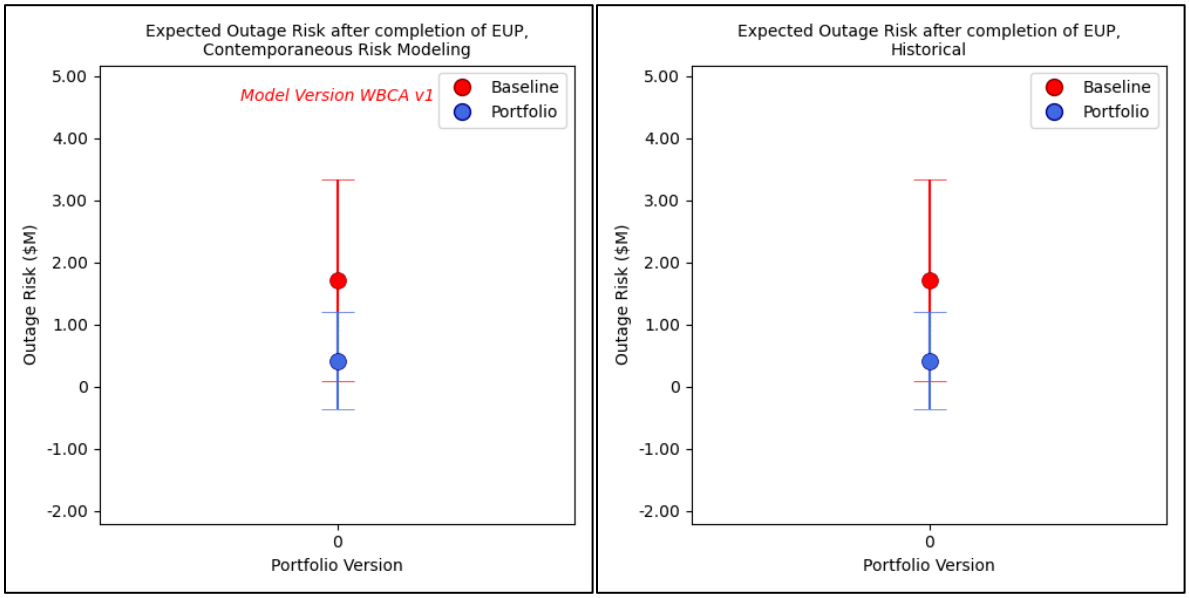

- Left: A plot showing the mean and standard deviation of the Ignition Likelihood's Baseline (red) and modeled value after EUP mitigation (blue) of Circuit Segments in the Portfolio, using the most recent version of the model, WBCA v1. The x-axis denotes a different version of the Portfolio. Note that due to the skew of the likelihood distribution, mean and standard deviation are not representative of the center and spread of the distribution.
- Right: A plot showing the mean and standard deviation of the Ignition Likelihood's Baseline (red) and modeled value after EUP mitigation (blue) of Circuit Segments in the Portfolio, using the WBCA v1, which was most recent at the time the Portfolio was updated. Note that due to the skew of the likelihood distribution, mean and standard deviation are not representative of the center and spread of the distribution.

d. Outage Program Risk

Figure PCS-13D shows a decrease in the system's Outage Program Risk associated with implementation of Portfolio 0.

FIGURE PCS-13D
KDMM DEVELOPMENT: CHANGES IN PORTFOLIO OUTAGE PROGRAM RISK

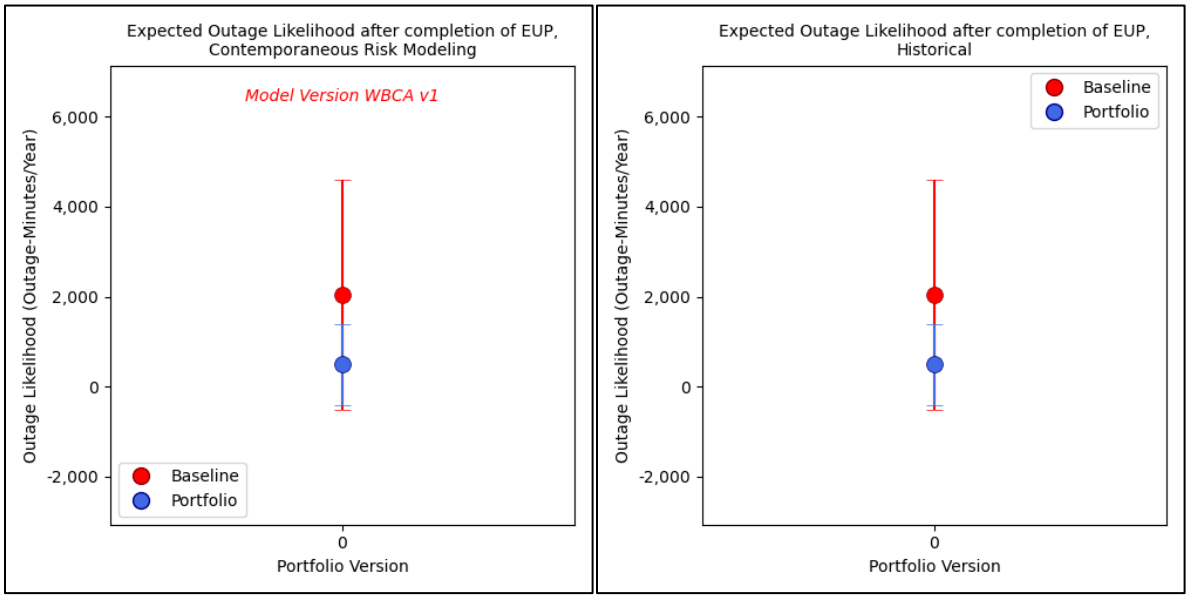

- Left: A plot showing the mean and standard deviation of the Outage Program Risk's Baseline (red) and modeled value after EUP mitigation (blue) of Circuit Segments in the Portfolio, using the most recent version of the model, WBCA v1. The x-axis denotes a different version of the Portfolio. Note that due to the skew of the risk distribution, mean and standard deviation are not representative of the center and spread of the distribution.
- Right: A plot showing the mean and standard deviation of the Outage Program Risk's Baseline (red) and modeled value after EUP mitigation (blue) of Circuit Segments in the Portfolio, using the WBCA v1, which was most recent at the time the Portfolio was updated. Note that due to the skew of the risk distribution, mean and standard deviation are not representative of the center and spread of the distribution.

e. Outage Program Consequence and Likelihood

KDMM graphs are not produced for Outage Program Consequence, as EUP mitigation does not modify the consequence of a PSPS or EPSS related outage, thus the modeled value after EUP mitigation is unchanged.

Figure PCS-13E reflects a reduction in the system's Outage Program Likelihood as a result of implementing Portfolio 0.

FIGURE PCS-13E
KDMM DEVELOPMENT: CHANGES IN PORTFOLIO OUTAGE PROGRAM LIKELIHOOD

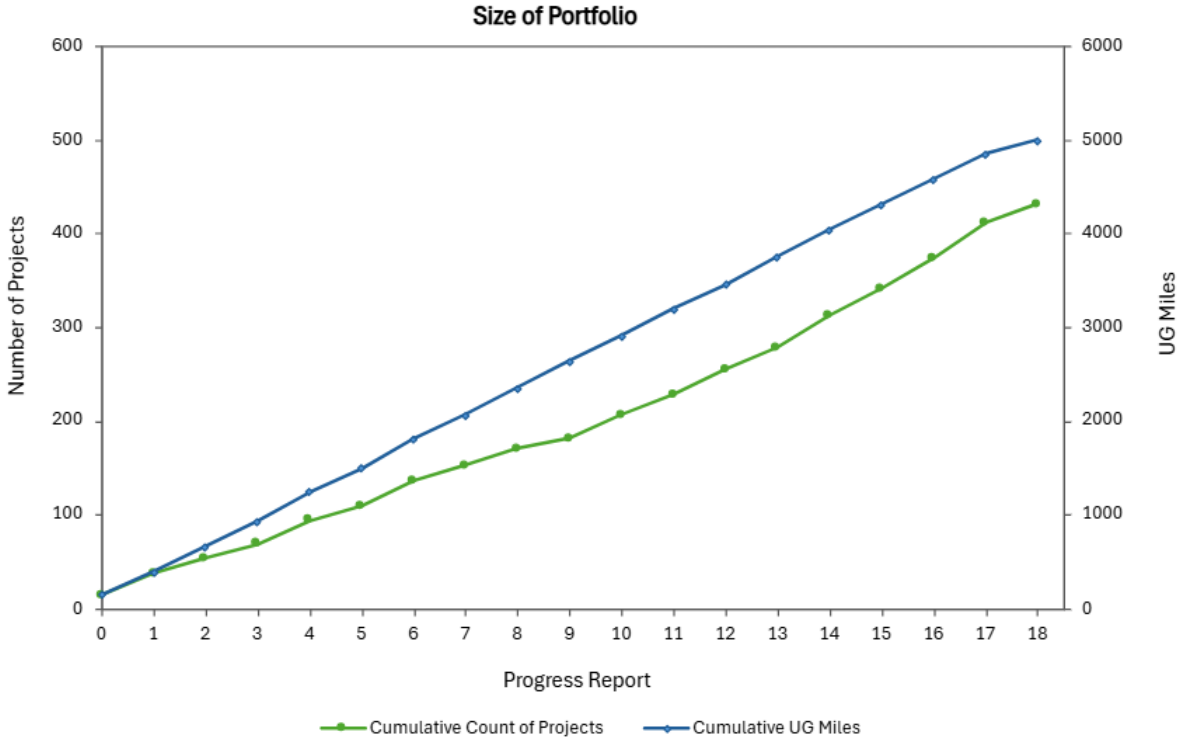

- Left: A plot showing the mean and standard deviation of the Outage Program Likelihood's Baseline (red) and modeled value after EUP mitigation (blue) of Circuit Segments in the portfolio, using the most recent version of the model, WBCA v1. The x-axis denotes a different version of the Portfolio. Note that due to the skew of the likelihood distribution, mean and standard deviation are not representative of the center and spread of the distribution.
- Right: A plot showing the mean and standard deviation of the Outage Program Likelihood's Baseline (red) and modeled value after EUP mitigation (blue) of Circuit Segments in the Portfolio, using the WBCA v1, which was most recent at the time the Portfolio was updated. Note that due to the skew of the likelihood distribution, mean and standard deviation are not representative of the center and spread of the distribution.

2. Size of Portfolio

Figure PCS-14, below, shows the size of the Portfolio based on the number of Undergrounding Projects and total underground circuit miles. It includes the first 28 Projects in Portfolio 0.

The projected growth shown in the graph assumes scoping approximately 45 underground miles per month, which drives the rate at which the Portfolio will expand over time. PORTFOLIO DEVELOPMENT OVER PROGRESS REPORT

Mitigation Effectiveness White Paper

1. WBCA 1.0 Mitigation Effectiveness Values for Undergrounding and Alternative Mitigations

1.1. Background

This White Paper documents the mitigation effectiveness values used to support circuit-segment-level comparisons of undergrounding and alternative mitigation strategies within PG&E's Wildfire Benefit Cost Analysis ("WBCA") model. This attachment documents the effectiveness assumptions applied to Wildfire Risk, Public Safety Power Shutoff ("PSPS") Risk, Enhanced Powerline Safety Settings ("EPSS") Risk, Baseline Outage Risk, and Public Contact with Intact Energized Electric Equipment ("PCEEE") Risk, so that the WBCA model can consistently evaluate each mitigation alternative across the risk categories included in the analysis.

Mitigation effectiveness represents the degree to which a mitigation measure reduces modeled risk. It provides a point estimate of how much risk is avoided or reduced as a result of implementing a specific Electric Undergrounding Plan ("EUP") mitigation alternative. These effectiveness values are informed by PG&E's Wildfire Mitigation Effectiveness Dataset, which evaluates mitigation performance based on historical outage combinations and associated ignition risk characteristics.[1]

Mitigation effectiveness is applied to baseline (unmitigated) risk to calculate residual (post-mitigation) risk. The effectiveness inputs reflect mitigation performance across a range of outage event combinations based on historical events observed in High Fire Thread District ("HFTD") areas and evaluated by Subject Matter Experts ("SMEs").

PG&E considered the following mitigation alternatives:

1. Undergrounding Primary Distribution Lines ("UG Primary")
2. Overhead Hardening ("OH")
3. Remote Grid

PG&E applied these mitigation alternatives to the following sources of risk:

1. Wildfire Risk
2. Public Safety Power Shutoff ("PSPS") Risk
3. Enhanced Powerline Safety Settings ("EPSS") Risk
4. Baseline Outage Risk
5. Public Contact with Intact Energized Electric Equipment ("PCEEE") Risk

Mitigation effectiveness plays two primary roles within the Wildfire Benefit Cost Analysis ("WBCA") Model. First, mitigation effectiveness is used to quantify benefits included in

---

[1] See Attach. B, WP006 (WBCA Whitepaper), Section 2.3.

the Benefit-Cost Ratio ("BCR").[2] Second, it is used to determine the amount of Overall Utility Risk ("OUR") reduced, including subsets of OUR reduction such as ignition risk and outage program risk.[3] Both applications rely on the same underlying mitigation effectiveness assumptions and values. The inputs and outputs of the WBCA model are intended to support mitigation selection in PG&E's EUP.[4]

2. Mitigation Effectiveness Methodology

2.1. UG Primary

2.1.1. Wildfire Risk

- **Systemwide Average Mitigation Effectiveness:** 98%

- **Methodology:** The Wildfire Mitigation Effectiveness Analysis evaluates outage data from 2015 through 2024. Each outage is characterized using four attributes that, when combined, create a unique outage profile:

  a. Basic cause (e.g., vegetation)
  b. Supplemental cause (e.g., tree branch contacting line)
  c. Equipment involved (e.g., overhead conductor)
  d. Equipment condition (e.g., normal, broken, wire on ground)

  These attribute combinations allow SMEs to review outages with similar characteristics and qualitatively assess mitigation effectiveness. The Mitigation Percentage in the table below describes how effective the mitigation alternative would be in preventing ignition from each unique outage scenario. SMEs assign one of the following Effectiveness Levels to each unique outage scenario:

---

2 See Attach. B, WP006 (WBCA Whitepaper), Section 3.1.

3 See Attach. B, WP006 (WBCA Whitepaper), Sections 2.3 and 3.1.4-3.1.5.

4 See Attach. B, WP006 (WBCA Whitepaper), Section 1.1.

Effectiveness Level	Mitigation Percentage	SME Qualitative Rationale
None	0%	Will not affect the likelihood of a certain type of outage resulting in an ignition
Low	20%	Reduces likelihood minimally of a certain type of outage resulting in an ignition
Medium	40%	Reduces likelihood moderately of a certain type of outage resulting in an ignition
Medium-High	60%	Better than average likelihood of reducing a certain type of outage resulting in an ignition
High	70%	Significant reduction in likelihood, however, there is still a chance for outage events resulting in an ignition
Very High	90%	Addresses most outage concerns, but still leaves potential for outage events resulting in an ignition
All	100%	Eliminates likelihood of a certain type of outage occurring resulting in an ignition

To determine circuit-segment-level mitigation effectiveness, SMEs assign mitigation effectiveness values to unique outage scenarios defined by combinations of outage attributes (e.g., Basic Cause, Supplemental Cause, Equipment Type, and Equipment Condition), referred to as "failure modes." These failure mode effectiveness values are subsequently mapped to the 21 ignition likelihood sub drivers used in WDRM Version 4 and aggregated to develop a representative effectiveness value for each driver. The resulting driver-level effectiveness values are then applied to the corresponding ignition likelihood components for each circuit segment. Because each circuit segment has a unique ignition likelihood profile across the 21 sub-drivers, the mitigation effectiveness values are combined using a weighted-average approach based on each driver's relative contribution to ignition likelihood on that circuit segment. This produces a circuit-specific mitigation effectiveness value that reflects both the mitigation's ability to address individual failure mechanisms and the risk characteristics of the circuit segment being evaluated. Based on Energy Safety's direction that EPSS be treated as operational in the baseline condition, wildfire mitigation effectiveness is measured relative to a system where EPSS is already in place, rather than against an unmitigated overhead system. Because EPSS is assumed to reduce approximately 60% of wildfire risk, undergrounding receives credit only for the incremental reduction in residual risk beyond that baseline.

As an example, if undergrounding reduces wildfire risk by approximately 98% relative to an unmitigated overhead system, the incremental reduction beyond the

EPSS baseline is 98% - 60% = 38%. Because EPSS has already reduced risk by 60%, only 40% of the original risk remains, calculated as 100% - 60% = 40%. Therefore, the incremental effectiveness of undergrounding against that residual risk would be 38% / 40% = 95%. Accordingly, while undergrounding continues to reduce approximately 98% of wildfire risk where applied, it is credited with approximately 95% effectiveness against the residual wildfire risk that remains after EPSS has already been applied. This example is intended solely to illustrate the baseline adjustment methodology using representative systemwide averages. Actual circuit-segment-level mitigation effectiveness will vary based on the relative weighting of the 21 ignition likelihood drivers for the specific project being evaluated. Consequently, project-specific incremental effectiveness values may be higher or lower than the average 95% value depending on the circuit segment's unique ignition risk profile and the mitigation's effectiveness against the drivers contributing to that risk. This approach ensures that benefits are not double counted and that each mitigation is evaluated based on the additional risk reduction it provides relative to existing operations.

2.1.2. PSPS Risk

- **Systemwide Average Mitigation Effectiveness:** 100%

- **Methodology:** The UG Primary mitigation is assumed to fully eliminate PSPS risk by removing the overhead infrastructure that necessitates PSPS events under elevated fire potential conditions. As described in the PSPS Risk Model Documentation,[5] the PSPS risk attributed to a given circuit segment already reflects both network effects and the geographic extent of weather events. Specifically, the risk assigned to a circuit segment is apportioned across upstream circuit segments and accounts for the fact that PSPS events do not always encompass an entire circuit, with scope varying based on the location and extent of the underlying weather conditions. Consequently, the risk attributed to a circuit segment has already been discounted to recognize that some outage risk cannot be fully eliminated until upstream circuit segments are also mitigated and that only portions of a circuit may be affected during a given PSPS event. Additionally, consistent with the PSPS Risk Model Documentation, all outage risk associated with a PSPS event, including outages experienced on the circuit segment itself and on downstream segments due to upstream de-energization, is attributed to the applicable circuit segment.

---

5 See Attach. B, WP020 (EUP PSPS v1 Risk Model Documentation), Section 3.1.

2.1.3. EPSS Risk

- **Systemwide Average Mitigation Effectiveness:** 100%

- **Methodology:** UG Primary is assumed to fully eliminate EPSS events where installed. Therefore, EPSS risk is treated as 100% mitigated under this alternative.

2.1.4. Baseline Outage Risk

- **Systemwide Average Mitigation Effectiveness:** 71%

- **Methodology:** The estimated Baseline Outage (i.e., non-PSPS and non-EPSS caused) mitigation effectiveness of undergrounding primary Distribution Overhead assets is evaluated by comparing historic reliability indices (SAIDI) attributed to Distribution Overhead and Distribution Underground assets normalized by their respective mileages.

    - **Reliability Indices (SAIDI):** Historic Reliability Indices (SAIDI) data attributed to outages on Distribution Overhead and Distribution Underground assets are summed to yield $S(SAIDI_{OH})$ and $S(SAIDI_{UG})$, respectively. Outage events considered in the Reliability Indices dataset pertain to Distribution Circuit & Transformer-Only outages; excluding Planned, PSPS, and Independent System Operator ("ISO") outages; and including Major Event Day ("MED") outages and EPSS outages.

    - **Exposure (Mileage):** End-of-year primary line mileages for 2018 through 2024 are obtained from a Geographic Information Systems Analytics Intake Application ("GAIA") data pull performed on January 24, 2025 utilizing fields 'OHMILES' and 'UGMILES' from the data group 'PGE OWNED (ALL)'. The Mileages are then summed across years 2018 through 2024 for Distribution Overhead ('OHMILES') and Distribution Underground ('UGMILES'), yielding $S(Mileage_{OH})$ and $S(Mileage_{UG})$, respectively.

With the preceding parameters, mitigation effectiveness is evaluated as:

Formula

$$\boldsymbol{Mitigation\ Effectiveness} = \frac{(r_{OH} - r_{UG})}{r_{OH}} = 1 - \frac{r_{UG}}{r_{OH}}$$

$$where, for\ example, r_{OH} = \frac{S(SAIDI_{OH})}{S(Mileage_{OH})}$$

2.1.5. Public Contact with Intact Energized Electric Equipment (PCEEE) Risk

- **Systemwide Average Mitigation Effectiveness:** 54%

- **Methodology:** The estimated PCEEE mitigation effectiveness for UG Primary is evaluated by comparing historic rates of Equivalent Fatalities (EFAT) attributed to Distribution Overhead and Distribution Underground assets normalized by their respective mileages.

    - **Equivalent Fatalities (EFAT):** Historic Electric Incident Report (EIR) data from 2012 through 2024 is reviewed to identify events attributed to Distribution Overhead and Distribution Underground asset families ('DOVHD' and 'DUNDG,' respectively) that occurred from 2018 through 2024.

      The EFAT values are then summed across years 2018 through 2024 for incidents attributed to Distribution Overhead and Distribution Underground assets, yielding $S(EFAT_{OH})$ and $S(EFAT_{UG})$, respectively.

Formula

$$\boldsymbol{EFAT} = \text{Fatalaties} + (0.25 \text{ x Serious Injuries})$$

Where a Serious Injury equates to 25% of an Equivalent Fatality.

    - **Exposure (Mileage):** End-of-year primary line mileages for 2018 through 2024 are obtained from a Geographic Information Systems Analytics Intake Application ("GAIA") data pull performed on January 24, 2025 utilizing fields 'OHMILES' and 'UGMILES' from the data group 'PGE OWNED (ALL)'. The mileages are then summed across years 2018 through 2024 for Distribution Overhead ('OHMILES') and Distribution Underground ('UGMILES'), yielding $S(Mileage_{OH})$ and $S(Mileage_{UG})$, respectively.

With the preceding parameters, mitigation effectiveness is evaluated as:

Formula

$$\textbf{Mitigation Effectiveness} = \frac{(r_{OH} - r_{UG})}{r_{OH}} = 1 - \frac{r_{UG}}{r_{OH}}$$

$$where, for\ example, r_{OH} = \frac{S(EFAT_{OH})}{S(Mileage_{OH})}$$

2.2. Remote Grid

2.2.1. Wildfire Risk

Systemwide Average Mitigation Effectiveness: 98%. Please note, wildfire risk mitigation effectiveness is the same for both the Remote Grid and UG Primary alternatives as each option removes the existing primary overhead line, thereby eliminating the same source of ignition risk. Consequently, both alternatives are assigned the same mitigation effectiveness value.

Methodology: The Wildfire Mitigation Effectiveness Analysis evaluates outage data from 2015 through 2024. Each outage is characterized using four attributes that, when combined, create a unique outage profile:

1. Basic cause (e.g., vegetation)
2. Supplemental cause (e.g., tree branch contacting line)
3. Equipment involved (e.g., overhead conductor)
4. Equipment condition (e.g., normal, broken, wire on ground)

These attribute combinations allow Subject Matter Experts ("SMEs") to review outages with similar characteristics and qualitatively assess mitigation effectiveness. The Mitigation Percentage in the table below describes how effective the mitigation alternative would be in preventing ignition from each unique outage scenario. SMEs assign one of the following Effectiveness Levels to each unique outage scenario:

Effectiveness Level	Mitigation Percentage	SME Qualitative Rationale
None	0%	Will not affect the likelihood of a certain type of outage resulting in an ignition
Low	20%	Reduces likelihood minimally of a certain type of outage resulting in an ignition
Medium	40%	Reduces likelihood moderately of a certain type of outage resulting in an ignition
Medium-High	60%	Better than average likelihood of reducing a certain type of outage resulting in an ignition
High	70%	Significant reduction in likelihood, however, there is still a chance for outage events resulting in an ignition
Very High	90%	Addresses most outage concerns, but still leaves potential for outage events resulting in an ignition
All	100%	Eliminates likelihood of a certain type of outage resulting in an ignition

To determine circuit-segment-level mitigation effectiveness, SMEs assign mitigation effectiveness values to unique outage scenarios defined by combinations of outage attributes (e.g., Basic Cause, Supplemental Cause, Equipment Type, and Equipment Condition), referred to as "failure modes." These failure mode effectiveness values are subsequently mapped to the 21 ignition likelihood drivers used in WDRM Version 4 and aggregated to develop a representative effectiveness value for each driver. The resulting driver-level effectiveness values are then applied to the corresponding ignition likelihood components for each circuit segment. Because each circuit segment has a unique ignition likelihood profile across the 21 sub-drivers, the mitigation effectiveness values are combined using a weighted-average approach based on each driver's relative contribution to ignition likelihood on that circuit segment. This produces a circuit-specific mitigation effectiveness value that reflects both the mitigation's ability to address individual failure mechanisms and the risk characteristics of the circuit segment being evaluated.

Based on Energy Safety's direction that EPSS be treated as operational in the baseline condition, wildfire mitigation effectiveness is measured relative to a system where EPSS is already in place, rather than against an unmitigated overhead system. Because EPSS is assumed to reduce approximately 60% of wildfire risk, Remote Grid receives credit only for the incremental reduction in

residual risk beyond that baseline. As an example, if Remote Grid reduces wildfire risk by approximately 98% relative to an unmitigated overhead system, the incremental reduction beyond the EPSS baseline is 98% - 60% = 38%. Because EPSS has already reduced risk by 60%, only 40% of the original risk remains, calculated as 100% - 60% = 40%. The incremental effectiveness of Remote Grid against that residual risk is therefore 38% / 40% = 95%. Accordingly, while Remote Grid continues to reduce approximately 98% of wildfire risk relative to an unmitigated overhead system, it is credited with approximately 95% effectiveness against the residual wildfire risk that remains after EPSS has already been applied. This example is intended solely to illustrate the baseline adjustment methodology using representative systemwide averages. Actual circuit-segment-level mitigation effectiveness will vary based on the relative weighting of the 21 ignition likelihood drivers for the specific project being evaluated. Consequently, project-specific incremental effectiveness values may be higher or lower than the average 95% value depending on the circuit segment's unique ignition risk profile and the mitigation's effectiveness against the drivers contributing to that risk. This approach ensures that benefits are not double counted and that each mitigation is evaluated based on the additional risk reduction it provides relative to existing operations.

2.2.2. PSPS Risk

- **Systemwide Average Mitigation Effectiveness:** 100%

- **Methodology:** The Remote Grid mitigation alternative is assumed to fully eliminate the need for PSPS events by removing reliance on overhead infrastructure that creates wildfire ignition risk under high-risk weather conditions. Furthermore, Remote Grid systems are electrically isolated and not connected to the broader grid environment through which PSPS events are typically implemented. As a result, the underlying conditions that necessitate PSPS as an operational mitigation are not present under this alternative.

2.2.3. EPSS Risk

- **Systemwide Average Mitigation Effectiveness:** 100%

- **Methodology:** Remote Grid is assumed to fully eliminate EPSS events where applied. Therefore, EPSS risk is treated as 100% mitigated under this alternative.

2.2.4. Baseline Outage Risk

- **Systemwide Average Mitigation Effectiveness:** 0%

- **Methodology:** Mitigation effectiveness for Baseline Outage Risk under the Remote Grid mitigation alternative is assumed to be 0%. When outages occur within a remote grid configuration, they are often significant in scope and may require specialized personnel and extended travel times to complete repairs. As a result, outage durations may not be reduced relative to baseline conditions.

  Given these factors, and the limited historical performance data available for remote grid systems, PG&E does not currently have sufficient evidence to support a measurable improvement in baseline annual outage duration (e.g., SAIDI) for customers served by remote grids. Accordingly, no mitigation benefit is attributed to Baseline Outage Risk under this alternative

2.2.5. PCEEE Risk

- **Systemwide Average Mitigation Effectiveness:** 0%

- **Methodology:** Mitigation effectiveness for PCEEE risk under the Remote Grid mitigation alternative is assumed to be 0%, as the configuration does not reduce or eliminate the presence of energized electrical equipment or the potential for public interaction with that equipment.

2.3. OH

2.3.1. Wildfire Risk

- **Systemwide Average Mitigation Effectiveness:** 79%[6]

- **Methodology:** The Wildfire Mitigation Effectiveness Analysis evaluates outage data from 2015 through 2024. Each outage is characterized using four attributes that, when combined, create a unique outage profile:

  1. Basic cause (e.g., vegetation)
  2. Supplemental cause (e.g., tree branch contacting line)
  3. Equipment involved (e.g., overhead conductor)
  4. Equipment condition (e.g., normal, broken, wire on ground)

---

6 This effectiveness value reflects Overhead Hardening deployed in conjunction with EPSS/DCD. Because EPSS/DCD is assumed to be operational in the baseline condition, only the incremental risk reduction attributable to Overhead Hardening is captured in the resulting calculations.

These attribute combinations allow SMEs to review outages with similar characteristics and qualitatively assess mitigation effectiveness. The Mitigation Percentage in the table below describes how effective the mitigation alternative would be in preventing ignition from each unique outage scenario. SMEs assign one of the following Effectiveness Levels to each unique outage scenario:

Effectiveness Level	Mitigation Percentage	SME Qualitative Rationale
None	0%	Will not affect the likelihood of a certain type of outage resulting in an ignition
Low	20%	Reduces likelihood minimally of a certain type of outage resulting in an ignition
Medium	40%	Reduces likelihood moderately of a certain type of outage resulting in an ignition
Medium-High	60%	Better than average likelihood of reducing a certain type of outage resulting in an ignition
High	70%	Significant reduction in likelihood, however, there is still a chance for outage events resulting in an ignition
Very High	90%	Addresses most outage concerns, but still leaves potential for outage events resulting in an ignition
All	100%	Eliminates likelihood of a certain type of outage occurring resulting in an ignition

To determine circuit-segment-level mitigation effectiveness, SMEs assign mitigation effectiveness values to unique outage scenarios defined by combinations of outage attributes (e.g., Basic Cause, Supplemental Cause, Equipment Type, and Equipment Condition), referred to as "failure modes." These failure mode effectiveness values are subsequently mapped to the 21 ignition likelihood drivers used in WDRM Version 4 and aggregated to develop a representative effectiveness value for each driver. The resulting driver-level effectiveness values are then applied to the corresponding ignition likelihood components for each circuit segment. Because each circuit segment has a unique ignition likelihood profile across the 21 sub-drivers, the mitigation effectiveness values are combined using a weighted-average approach based on each driver's relative contribution to ignition likelihood on that circuit segment. This produces a circuit-specific mitigation effectiveness value that reflects both the mitigation's ability to address individual failure mechanisms and the risk characteristics of the circuit segment being evaluated.

Based on Energy Safety's direction that EPSS be treated as operational in the baseline condition, wildfire mitigation effectiveness is measured relative to a

system where EPSS is already in place, rather than against an unmitigated overhead system. Because EPSS is assumed to reduce approximately 60% of wildfire risk, OH paired with EPSS receives credit only for the incremental reduction in residual risk beyond that baseline. As an example, if OH paired with EPSS reduces wildfire risk by approximately 79% relative to an unmitigated overhead system, the incremental reduction beyond the EPSS baseline is 79% - 60% = 19%. Because EPSS has already reduced risk by 60%, only 40% of the original risk remains, calculated as 100% - 60% = 40%. The incremental effectiveness of OH against that residual risk is therefore 19% / 40% = 47.5%. Accordingly, while OH paired with EPSS reduces approximately 79% of wildfire risk, this mitigation alternative is credited only for the incremental effectiveness against the residual wildfire risk that remains after EPSS has already been applied. This example is intended solely to illustrate the baseline adjustment methodology using representative systemwide averages. Actual circuit-segment-level mitigation effectiveness will vary based on the relative weighting of the 21 ignition likelihood drivers for the specific project being evaluated. Consequently, project-specific incremental effectiveness values may be higher or lower than the average 47.5% value depending on the circuit segment's unique ignition risk profile and the mitigation's effectiveness against the drivers contributing to that risk. This approach ensures that benefits are not double counted and that each mitigation is evaluated based on the additional risk reduction it provides relative to existing operations.

2.3.2. PSPS Risk

- **Systemwide Average Mitigation Effectiveness:** 0%

- **Methodology:** The OH mitigation alternative does not reduce PSPS risk. This is because this mitigation alternative does not eliminate the underlying wildfire risk conditions that necessitate PSPS events as an operational mitigation. As a result, PSPS deployment would still be required under high-risk weather and system conditions, and no reduction in PSPS risk is attributed under this mitigation alternative.

2.3.3. EPSS Risk

- **Systemwide Average Mitigation Effectiveness:** 52%

- **Methodology:** The OH mitigation effectiveness methodology for EPSS risk is consistent with the methodology applied for Baseline Outage Risk under the OH mitigation configuration detailed below in Section 2.3.4. Accordingly, this mitigation alternative results in a 52% reduction in EPSS risk.

2.3.4. Baseline Outage Risk

- **Systemwide Average Mitigation Effectiveness:** 52%

- **Methodology:** The Baseline Outage mitigation effectiveness analysis evaluates outage data from 2015 through 2024. Each outage is characterized using four attributes that, when combined, create a unique outage profile:

    - Basic cause (e.g., vegetation)
    - Supplemental cause (e.g., tree branch contacting line)
    - Equipment involved (e.g., overhead conductor)
    - Equipment condition (e.g., normal, broken, wire on ground)

  These unique combinations allow Subject Matter Experts ("SMEs") to efficiently review outages with similar characteristics and quantitatively assess mitigation effectiveness. The effectiveness rating describes how effective the mitigation alternative would be in preventing ignition from each unique outage profile. SMEs assign one of the following effectiveness levels to each unique outage profile:

Effectiveness Level	Mitigation Percentage	SME Qualitative Rationale
None	0%	Will not affect the likelihood of a certain type of outage
Low	20%	Reduces likelihood minimally of a certain type of outage
Medium	40%	Reduces likelihood moderately of a certain type of outage
Medium-High	60%	Better than average likelihood of preventing a certain type of outage
High	70%	Significant reduction in likelihood, however, there is still a chance for outage events
Very High	90%	Addresses most outage concerns, but still leaves potential for outage events
All	100%	Eliminates likelihood of a certain type of outage

  These mitigation percentages are then combined across all outage profiles to produce a single, aggregated mitigation effectiveness of 52% for Baseline Outage Risk.

2.3.5. PCEEE Risk

- **Systemwide Average Mitigation Effectiveness:** 0%

Methodology: The OH mitigation alternative does not reduce PCEEE risk. This is because this mitigation alternative is primarily designed to address ignition related risks and system reliability risk, rather than risks associated with direct public interaction with equipment. As a result, the underlying exposure and hazard conditions that drive PCEEE risk remain unchanged under this mitigation alternative, and no reduction in PCEEE risk is attributed.

6	1/1/2033 - 12/31/2033	600	480	2,500	1,250	$3.30	$2.95	24.4	1,370	44.1	3,253
7	1/1/2034 - 12/31/2034	625	500	3,125	1,250	$3.36	$2.94	22.7	1,277	47.6	3,222
8	1/1/2035 - 12/31/2035	625	500	3,750	1,250	$3.42	$2.92	20.0	1,070	54.6	3,236
9	1/1/2036 - 12/31/2036	625	500	4,375	625	$3.49	$2.91	17.3	927	61.5	4,110
10	1/1/2037 - 12/31/2037	625	500	5,000	0	$3.56	$2.90	15.7	803	77.6	5,877
End/Total	12/31/2037	5,000	4,000	5,000	0			$208	$11,768	$453	$30,953

(a) Underground mileage is estimated by applying a 1.25 multiplier to the corresponding overhead mileage deenergized. The 2028 undergrounding mileage shown in the EUP Target/Timeline Table (250 miles) differs from the mileage approved in the 2026 WMP (400 miles). The difference is primarily due to the time needed to transition the program and its supporting structure to meet the EUP requirements. Once the EUP is approved, PG&E will update the WMP mileage at the appropriate time.

(b) Pre-construction miles are calculated as the sum of undergrounding miles required to be in the planning process in the next two years that are needed to meet execution targets. These miles reflect the number of miles passing Screen 3 and Screen 4. There is a two year lead time for pre construction miles (e.g., 650 miles in 2028 is the sum of planned miles for 2029 and 2030).

(c) To establish 2028 unit cost values, 2025 actual costs are escalated to 2028 dollars. The "Unit Cost Escalated" column reflects annual unit cost values further escalated from 2028 dollars to the dollar value in the applicable year (2028–2037). The "Unit Cost Unescalated" column reflects annual unit cost values presented in unescalated 2028 dollars and incorporates assumed unit cost reductions over time as program efficiencies are realized. Cost assumptions applied in the current WBCA model for Screen 2 are based on average 2028 unit costs; however, costs for individual projects may vary based on project-specific feasibility multipliers.

(d) Instantaneous and cumulative risk values represent unmitigated Wildfire and Outage Program Risk for all years prior to project completion, and post-mitigated risk from the year the project is completed onward. PG&E applies the Risk Model Impact Factor, climate escalation, and inflation adjustments as described in this section.

(e) Totals may not exactly equal the sum of individual values because figures are rounded independently.

Feedback Loop White Paper

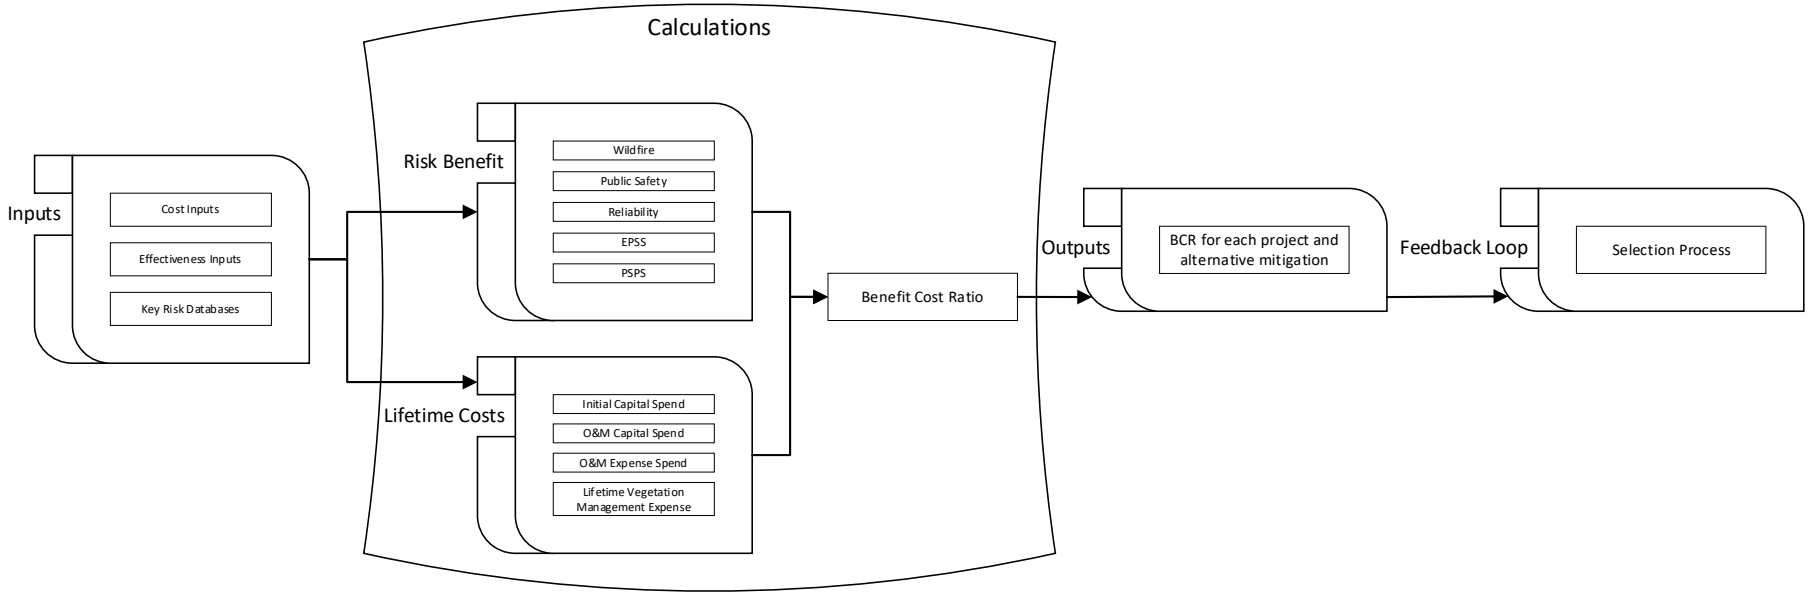

1. Overview of Feedback Loop

The Wildfire Benefit Cost Analysis (WBCA) Feedback Loop system allows PG&E to evaluate alternative system hardening strategies by calculating Benefit Cost Ratios (BCRs) across infrastructure approaches, including combinations of undergrounding, overhead hardening, and remote grid solutions. The feedback loop is designed to iteratively refine project-level WBCA results using updated scoping inputs, with a primary focus on incorporating revised cost assumptions, refining Public Safety Power Shutoff (PSPS) risk reduction estimates, and assessing hybrid mitigation configurations. This enables PG&E to evaluate how these targeted updates influence BCRs, risk reduction, and compliance with Project-Level Standards.

As illustrated in Figure 1 below, the WBCA feedback loop system leverages the calculations and outputs of WBCA to create new records of output metrics based on variable inputs.[1] Inputs are updated as part of the Screen 3 scoping process, and the feedback loop enables recalculation to reflect revised assumptions. For each record, the WBCA feedback loop system calculates various cost-benefit metrics, including BCRs. These output metrics are used to support comparison of alternative configurations and identify infrastructure approaches that maximize cost-effective risk reduction benefits over the asset's life. Additionally, the WBCA feedback loop system determines whether the considered scenario meets applicable Project-Level Standards by comparing calculated risk reduction metrics to the corresponding Project-Level Standard.

[1] See Attach. B, WP006 (WBCA Whitepaper) for additional information on the WBCA.

Figure 1: WBCA Model Diagram

2. Feedback Loop Process

2.1. Project Analysis, and Work Plan Selection

The feedback loop process involves creating feedback loop records, where each record documents the inputs, outputs, and corresponding calculations of a potential project implementing one or more mitigations on a circuit segment. The process begins by selecting the circuit segment to be associated with the project, as well as an analysis representing the current results of Screen 2 assessments used to inform the feedback loop calculations. A project then goes through several phases of analysis, with each phase categorized as a "work plan." During these analyses, the project goes through a feasibility study to determine whether it is feasible and appropriate for scoping. If feasible, the project is scoped and then is either considered scoped or determined to be infeasible. During this process, once a work plan and analysis are selected, the system displays the following circuit segment metrics including:

- Baseline costs and benefits
- Risk metrics
- Mitigation effectiveness factors
- Circuit segment characteristics

2.2. PSPS Risk Mitigation

From a modeling perspective, PSPS risks originate from PSPS event polygons, or extreme weather areas. The potential reduction in PSPS risk (i.e., PSPS Risk Mitigation) for a given project depends on the amount of primary overhead lines within each PSPS event polygon that will be removed. This evaluation is conducted by creating a PSPS mitigation scenario wherein overhead lengths to be removed from PSPS event polygons are specified. The anticipated PSPS Risk Mitigation is then evaluated by aggregating impacts from all PSPS event polygons with which a given circuit segment intersects.

2.3. Mitigation Type Selection

The feedback loop includes three mitigation types as well as an option to consider a combination of mitigations as a hybrid mitigation:

- **UG Primary Distribution Lines:** Primary distribution lines on the circuit segment are undergrounded.
- **Overhead Hardening (OH):** Primary distribution lines on the circuit segment are hardened with covered conductor.
- **Remote Grid:** Distribution lines are removed and replaced with remote grid infrastructure.

- **Hybrid Mitigations:** Distribution lines on the circuit segment are addressed by a combination of the preceding mitigation types – i.e., undergrounding, overhead hardening, and/or remote grid solutions.

When creating a feedback loop record, users specify the Mitigation Type for the record and enter refined inputs into the system, as described in section "3. Feedback Loop Mitigation Type Inputs."

2.4. Feedback Loop Record Submission

Once the feedback loop inputs described in Section 3 are submitted, the WBCA feedback loop record is created and the system produces the estimated cost and benefit metrics and identifies whether the project level standards are met.

See Section 4 and Attach. B, WP006 (WBCA Whitepaper) for the formulas for the cost and benefit metrics applied within the WBCA Feedback Loop.

2.5. WBCA Feedback History

The WBCA Feedback history allows PG&E to view details of the WBCA feedback loop records. Each WBCA record is assigned a status: Draft, Pre-DSM (Desktop Scoping Meeting), or Final. Final represents the actual plan to be executed, and only one record per circuit segment can be marked as final.

Additionally, PG&E can duplicate an existing WBCA feedback loop record for modification to incorporate new or updated information. For example, a record may be duplicated for modification when updated cost information becomes available or when risk model results informing the WBCA feedback loop evaluations need to be updated. When duplicating and modifying a record, a new record is generated to preserve the historical record.

3. Feedback Loop Mitigation Type Inputs

Once a mitigation is selected, the following inputs are entered into the system by PG&E. The required fields vary depending on the mitigation type:

- The UG Primary mitigation type allows users to enter undergrounding miles, undergrounding unit cost, miles removed for undergrounding, idle miles removed, cost of removing idle miles, excluded miles, privately owned miles, and refined PSPS risk reduction estimates.
- The OH mitigation type allows users to enter OH system hardening miles, OH system hardening unit cost, idle miles removed, cost of removing idle miles, excluded miles, and privately owned miles.

- The Hybrid mitigation type allows users to enter undergrounding miles, undergrounding unit cost, miles removed for undergrounding, overhead hardening miles, overhead hardening unit cost, idle miles removed, cost of removing idle miles, excluded miles, privately owned miles, remote grid cost, remote grid miles, and refined PSPS risk reduction estimates.

See Table 1 below for feedback loop mitigation type inputs.

TABLE 1
FEEDBACK LOOP MITIGATION TYPE INPUTS AND DESCRIPTIONS

Input	Description
Undergrounding Miles	Miles of lines to be undergrounded upon scope completion.
Undergrounding Unit Cost ($M)	Initial capital cost of installing underground per mile. Includes the primary unit cost ("UG primary").
Overhead Hardening (OH) System Hardening Miles	Miles of lines to be hardened upon scope completion.
Overhead Hardening (OH) System Hardening Unit Cost ($M)	Cost of implementing system hardening per mile on OH conductor.
Removal Idle Miles	Miles of idle overhead lines removed upon scope completion.
Removal Idle Mile Cost ($M)	Cost of removing idle lines per mile.
Remote Grid Miles	Miles of overhead lines that will be removed and replaced by Remote Grid.
Remote Grid Installation Cost ($M)	Lump sum cost of installing Remote Grid.
Remote Grid O&M Cost ($M)	Lump sum O&M costs for Remote Grid.
Excluded Miles	Miles of overhead lines already hardened, planned for hardening, or ineligible for scoping. These miles will be excluded from the BCR calculation.
Privately Owned Miles	Miles of privately owned primary overhead lines. These miles will be excluded from the BCR calculation.
Miles Removed for Undergrounding	Miles of overhead that will be replaced by underground lines. These miles are used to calculate residual conductor miles for risk mitigation.
PSPS Mitigated Benefit ($M)	Estimated reduction in PSPS risk due to removal of overhead lines within event polygons

4. Calculations

The calculation of cost and benefit metrics applied within the WBCA Feedback Loop is consistent with the methodology described in Attach. B, WP006 (WBCA Whitepaper). These calculations are operationalized and iteratively updated within the Feedback Loop to reflect revised project inputs and mitigation configurations.

5. Conclusion

PG&E's WBCA feedback loop system is designed to support consistent, repeatable, and transparent decision-making for circuit segment-level mitigation selection. It produces cost and benefit metrics for a variety of mitigation scenarios and can be updated as inputs, scope, and assumptions evolve, enabling iterative re-evaluation as project information matures. In this way, the system serves as a decision-support framework that allows PG&E to compare alternative mitigation configurations, assess their relative cost-effectiveness and risk reduction, and inform selection of the mitigation approach that best advances program objectives.

Section 1

Project Overview and Defining Key Terms

Purpose

The engagement between Marsh and PG&E consists of **two primary wildfire models** that are assessed for both pre-EUP (2026-2027) and post-EUP (2028-2037), based on 5,000 miles of undergrounding as part of PG&E's work plans that were received by Marsh in **August 2026 for this analysis.**

Marsh evaluated the pre- and post- EUP impact on PG&E's distribution poles and how undergrounding impacts modeled PG&E attributable wildfire losses to residential properties, businesses, and the surrounding community. The analysis for the surrounding community includes a climate change impact model and the effect on homeowner's insurance.

Defining Key Terms

Loss	The outputs of Marsh's modeling are based on simulated years of possible financial losses to PG&E. "Loss" refers to the amount of financial liability resulting from wildfire events payable by PG&E.
Average Annual Loss (AAL)	With all simulated financial losses, the average amount of loss across all the years is referred to as the "AAL."
1-in-100 Year VaR	This is the 99th percentile worst year (largest financial loss) PG&E can experience. This is also interpreted as the worst year out of 100 simulated years. This is also referred to as "extreme loss."
1-in-100 Year TVaR	The average of all years where losses are worse than the 1-in-100 Year VaR. This is interpreted as the volatility in the tail-end beyond the 99th percentile. This is also referred to as "most extreme loss."
Catastrophic Loss	The worst-case catastrophic years that PG&E could experience is characterized by the range of losses from the 1-in-100 Year VaR (extreme loss) to the 1-in-100 Year TVaR (most extreme loss).

PG&E Territory	Marsh's modeling starts by simulating wildfires across the state of California. Any simulated wildfire that is located within PG&E's service area is considered a part of the PG&E Territory losses.
Modeled PG&E Reportable Ignitions (Attributable)	Within Marsh's wildfire model simulations, any modeled wildfire that Marsh statistically determines is attributable to an ignition by a PG&E asset is a part of the PG&E modeled Attributable losses.

Loss Modeling Results and Metrics in Context For all Segments of Analysis

In order to best synthesize these wildfire loss results, Marsh focused on two key metrics:

- Catastrophic loss, measured as Annual Probable Maximum Loss (APML) which Marsh anchored on a 1-in-100 years point, or 1%.
- Average loss, measured as Annual Average Loss (AAL).

Together, these metrics help describe the statistical range of possible losses associated with wildfires. Catastrophic losses can be understood as very low frequency (1%) but high severity events. These events are statistically probable in any given year, or in particularly extreme years, more than once. Because of the nature of stochastic modeling, this metric reflects a possible but technically still hypothetical loss. In other words, a reduction in APML does not necessarily mean guaranteed savings in a given year. However, because investments in risk mitigation or risk reduction are by definition investments in reducing both real and potential impacts from loss events, APML reduction is still one of two primary goals when considering risk expenditures.[1]

Average annual loss is the average of all modeled losses, including years with no losses, and reflects the statistically most probable outcome in any given year. While still a modeled loss, this metric represents most likely losses in any given year. As such, AAL reduction can be understood as expected "real" annual savings.

[1] Risk transfer (insurance) return on investment (ROI) analysis typically contemplates real savings (average loss reduction) and some form of catastrophic loss reduction, with transfer efficiency often primarily based on catastrophic loss reduction.

Marsh

Section 2
Community Risks

Key Takeaways

- Based on Cal-Fire historical data, approximately 9 percent of wildfires in PG&E's service area from 2014 to 2024 were caused by "Electrical Power" infrastructure. The same infrastructure is also responsible for 81 percent of the $41.1B in wildfire losses over the same time horizon.
- PG&E's EUP will help mitigate significant residential and commercial losses due to wildfire risk associated with modeled PG&E reportable ignitions by a modeled average annual loss of approximately $24M, or a 21 percent reduction.
- Extreme losses for residential and commercial properties associated with modeled PG&E reportable ignitions, representing the 99th percentile or 1-in-100 year worst loss, are expected to decrease by approximately $533M or 20 percent due to PG&E's EUP.
- Looking further into the tail-end scenarios, the most extreme losses associated with modeled PG&E reportable ignitions for residential and commercial properties are expected to decrease by approximately $699M or 12 percent.
- Modeled results estimate that PG&E's EUP reduces the economic impacts of wildfire for residential properties by reducing:
  - Average annual losses by approximately $21M or 21 percent;
  - Extreme losses (99th percentile or 1-in-100 year worst loss) by approximately $465M or 19 percent; and
  - Most extreme losses by approximately $627M or 12 percent.
- Modeled results estimate that PG&E's EUP reduces the economic impacts of wildfire for commercial properties by reducing:
  - Average annual losses by approximately $3M or 20 percent;
  - Extreme losses (99th percentile or 1-in-100 year worst loss) by approximately $67M or 21 percent; and

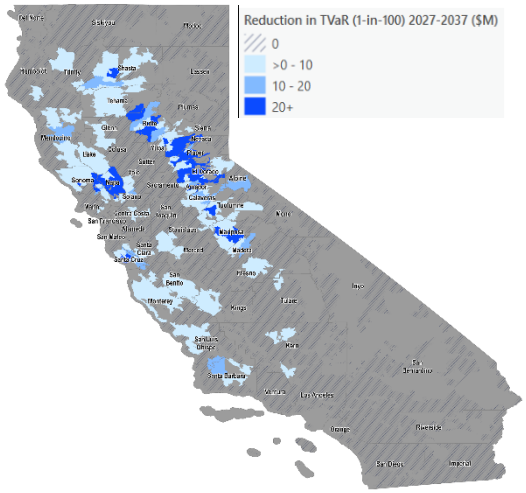

Figure 2-1: Catastrophic Residential Loss Change by Zip Code (Most Extreme Loss)

– Most extreme losses by approximately $77M or 11 percent.

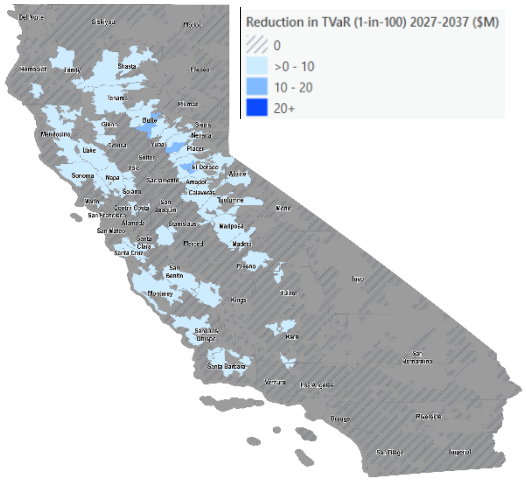

Figure 2-2: Catastrophic Commercial Loss Change by Zip Code (Most Extreme Loss)

Methodology Overview

The Marsh approach used simulation techniques to model PG&E's estimated wildfire liability attributable to PG&E distribution assets. Low frequency catastrophe events such as wildfire and especially for utility-associated wildfire require some deviation from actuarial approaches that rely primarily on historical losses. Marsh's approach accounts for the infrequency of historical events and is in line with catastrophe modeling techniques often used by the insurance and reinsurance industries for these types of losses.

The Marsh analysis used AIR Worldwide Corporation's ("AIR") wildfire event catalogue ("catalogue") and its industry exposure database (IED) as available through AIR's Wildfire Model V12 as implemented in its Touchstone platform. Marsh is not using Touchstone's native probabilistic modeling capabilities. Instead, the Marsh approach used the full event catalogue and the IED as the basis for a Marsh-developed probabilistic Monte Carlo simulation.

Using the AIR event catalogue from the V12 Wildfire Model, Marsh implemented a Monte Carlo simulation that sampled against the AIR wildfire events within the catalogue. As AIR notes in its 2018 documentation, such a simulation would "give mathematical representation to the physical phenomena of catastrophe events in order to evaluate the potential damage and insured losses that can occur." Furthermore, the Marsh approach, like the AIR approach in 2018, is probabilistic, meaning that "the results of the modeling are expressed in terms of probabilities" with results "expressed in terms of a probability distribution, also known as a loss distribution."[2]

The Marsh Monte Carlo simulation sampled against the AIR event catalogue, which provided wildfire location and severity data but lacked ignition cause. To build in the ignition cause, Marsh applied geofencing and probabilistic filters to determine which modeled events could stochastically by attributable to PG&E's distribution assets (utility-caused).

[2] AIR, "Cal Phoenix Re 2018-1 – Offering Circular Supplement No.1", A-1.

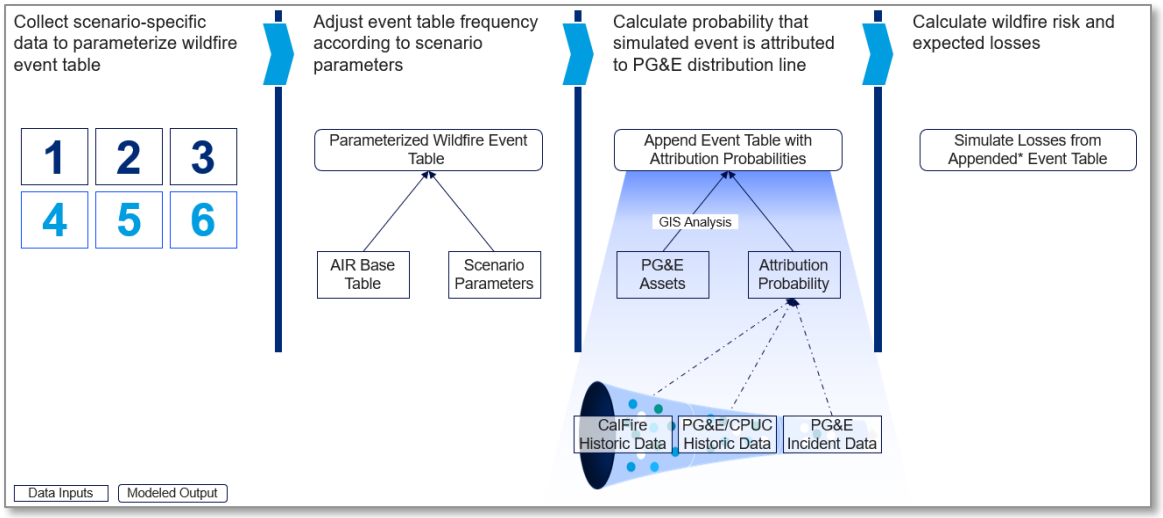

Figure 2-3: Community Risks Base Model Methodology

Probabilistic Attribution

Using historical analysis of California wildfires, their losses, and determined ignition causes, Marsh developed a probability of attribution that assessed the likelihood of attribution back to a PG&E distribution asset based on final simulated fire loss.

Marsh developed a composite historical data set from Cal-Fire, the California Public Utility Commission's (CPUC) PG&E reported ignitions, PG&E internal ignition data, PG&E internal loss data, publicly available reported losses from wildfire, Marsh and Guy Carpenter subject matter expert interviews, and PG&E subject matter expert interviews. This data set encompassed ignitions and wildfires from 2014-2023. Marsh analyzed this data set to determine what fire characteristics (acres burned, estimated financial losses, reported fatalities, seasonality, weather conditions) were most predictive of a given ignition type. This analysis concluded that estimated losses were by far the strongest predictor of ignition source, including utility-asset related causes.

Based on this conclusion, Marsh, in partnership with subject matter experts from Guy Carpenter, determined attribution likelihood of a simulated wildfire event against that fire's cumulative losses as available in the event catalogue data.

In order to develop the probability of attribution formula, Marsh computed a maximum bound for the probability of attribution based on historical PG&E attribution rates of reported wildfires.

Between 2014 and 2023, PG&E yearly attribution rates associated with a distribution asset for reported wildfires in the data set ranged from 0.13% to 47.41%. However, when compared to PG&E's Wildfire Safety Division (WSD) internal data on specific causes of ignition, these historical attribution rates can be further broken down by individual WSD driver cause. Within that more refined view, PG&E's historical distribution asset attribution drops to

0.00% - 47.07%. Because this is a known historical range of attribution rates and considering that PG&E's wildfire risk has likely reduced further given its continued mitigation activities, Marsh computed a weighted average of the historical outcomes (42.3%) as its "maximum" bound for probabilistic attribution given a simulated wildfire event loss.

Not surprisingly, there were years in the composite data set where no PG&E assets were associated with a reported wildfire against a specific WSD driver. Following discussion with wildfire modeling experts from Guy Carpenter, Marsh selected a non-zero minimum (0.05%) floor instead of the historical zero to err on the conservative side. The selected floor avoided a "zero risk" possibility but was still small enough so not to unnecessarily skew potential losses higher.

Each simulated loss event, after it had been determined to be within the PG&E service area and distribution asset geo fence, was then probabilistically determined to be "attributed" to PG&E based on the cumulative losses as reported in the AIR event catalogue for that event.

AIR Catalogue and IED

The Marsh analysis uses the 10,000-year AIR Worldwide Corporation's ("AIR") wildfire event catalogue ("catalogue") and its industry exposure database (IED) as available through AIR's Wildfire Model V11 as implemented in its Touchstone platform. Marsh is not using Touchstone's native probabilistic modeling capabilities. Instead, the Marsh approach uses the full event catalogue and the IED as the basis for a Marsh-developed probabilistic Monte Carlo simulation.

The AIR wildfire model is an event-based model that stochastically captures wildfire risk to property within the 13 westernmost US states, including California. Marsh only used the California catalogue for its analysis. The catalogue is a collection of simulated events that capture the frequency, severity, location and other characteristics of the entire spectrum of plausible wildfire ignitions and associated loss outcomes.

Events in the catalogue include ignition points, total area burned, spatial distribution of each simulated wildfire, and associated losses. Though the catalogue itself is 10,000 years, years may have more than one wildfire, resulting in hundreds of thousands of wildfire events in the catalogue 100 acres or greater.

Fire size, frequency, and seasonality of simulated fires are based on several factors but primarily reflect simulated weather and fuel conditions within an ecoprovince. Ecoprovinces are regions with similar ecosystems, climate, and vegetation and these physical elements are key drivers of fire behavior. Frequency of events is also driven by historical total area burned per year and per month in each ecoprovince. Historical fire data is drawn from the USDA Forest Service's Fire Occurrence Database (FOD).

Wildfire event damage reflects a combination of fire intensity data and property exposure characteristics. AIR models wildfire intensity within its proprietary spread model, and includes fire characteristics such as flame length, rate of spread, and fuels reaction intensity. Building exposure characteristics include construction type, occupancy, roofing and siding material, and defensible spaces.

Marsh

Section 3
Climate Change

Key Takeaways

- Expected average annual losses and extreme losses from wildfires across PG&E's service territory in 2037 are expected to increase substantially, by almost 11 percent, due to climate change. Specifically, average annual losses are expected to increase by $250M and extreme losses are expected to increase by $2.0B.

Figure 3-1: Change in Extreme Loss due to Climate Change only across PG&E Service Territory (2028 – 2037)

- The modeled reduction in risk from PG&E's EUP is outpaced by the expected increase in risk due to climate change, resulting in an increased average annual loss of approximately $15M or 1 percent, as well as an increase in the most extreme losses of approximately $1.7B or 5 percent to residential and commercial properties across PG&E's service territory. It is important to note that without the impact of the EUP, these increases would be far more significant, with annual losses expected to increase by $179M or 7 percent and most extreme losses increasing by $2.5B or 7 percent. Regardless, 30 counties are expected to experience a decrease in extreme losses over the next decade.

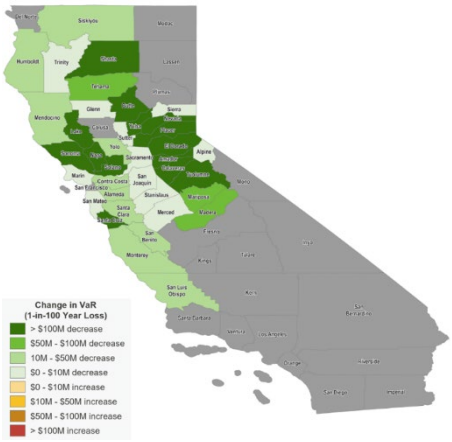

Figure 3-2: Reduction in Extreme Loss across PG&E Service Territory due to Undergrounding (2037)

	Increase in Risk Attributable to Climate Change (excl. EUP)	Increase in Risk Attributable to Climate Change (incl. EUP)	Difference
Average Annual Loss	$179M (7.0%)	$15M (0.6%)	$164M (91.8%)
Extreme Loss	$1.4B (6.9%)	$177M (0.9%)	$1.2B (87.5%)
Most Extreme Loss	$2.5B (7.4%)	$1.7B (4.8%)	$869M (34.3%)

Figure 3-3: Reduction in Losses Across PG&E Service Territory including and excluding EUP Impact (2028 – 2037)

Marsh

Methodology Overview

The climate change analysis models PG&E's wildfire risk and the effect of PG&E's EUP undergrounding plans over the period of 2028-2037 under a "worst case" scenario as defined by the Cal-Adapt RCP 8.5 pathway.

Climate Change Public Models

There are 2 major climate change public models that most regulators currently rely on:

- RCP (Representative Concentration Pathways)
  - RCPs are a set of scenarios that describe the potential future radiative forcing resulting from different levels of greenhouse gas concentrations.
  - As the previous CMIP5 (2013) scenarios, RCPs range from RCP 2.6 (best case) to RCP 8.5 (worst case).
  - RCP 8.5 represents the climate change scenario in which the concentration of emissions results in radiative forcing greater than 8.5 watts per square meter, resulting in a total warming of approximately 4.0 degrees Celsius by 2100. This pathway is commonly referred to as the "worst case" climate scenario and provides an extreme set of conditions against which to run our wildfire model.
- SSP (Shared Socioeconomic Pathways)
  - SSPs are a set of scenarios that describe different possible paths of development in terms of demographic, economic, technological, and social factors.
  - As the most recent CMIP6 (2021) scenarios, SSP-RCP Scenarios range from SSP1-1.9 to best case to SSP3-7.0 and SSP5-8.5 worst case.

Despite regulator movement towards SSP3-7.0, public models largely still rely on RCP 8.5. Given the historic preference for RCP 8.5 scenarios, existing publicly available models are more fine-tuned for Marsh's wildfire modeling. Cal-Adapt and other key sources have not yet released broadly applicable SSP3-7.0 models.

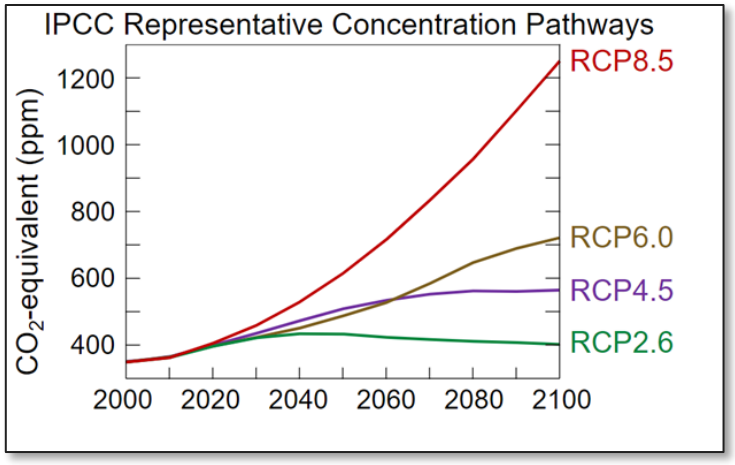

Figure 3-4: RCP (Representative Concentration Pathways)

Approach

To assess the impact of climate change, Marsh employed the RCP 8.5 carbon emissions scenario. Marsh chose those conditions to test extreme conditions and how undergrounding might change wildfire risk. Marsh did not assess the likelihood of those condition sets occurring.

The Cal-Adapt RCP 8.5 datasets provide acres burned from wildfires for every year until 2099. Marsh leveraged all 4 RCP 8.5 models available (CanESM2, CNRM-CM5, HadGEM2-ES, MIROC5) to compile a dataset of acres burned for all California counties within PG&E's service territory over the 100-year period of 2000-2099.

For each county, the 100 years of data were fitted to 5 different distributions (linear, exponential, binomial, trinomial, logarithmic) and the distribution with the best fit was chosen.

For each fitted distribution, a multiplier 'ClimateMultiplier' was calculated for the increase in wildfire risk from 2028-2037 to match the period of PG&E's EUP undergrounding plans.

Using the fitted distributions, Marsh applied each county's calculated 2028-2037 climate change multipliers onto the previously completed community risk results.

These final results show PG&E's wildfire risk in the case that climate change follows the RCP 8.5 pathway.

Marsh

Section 4
PG&E Assets and Direct Losses

Key Takeaways

- PG&E currently faces an estimated average annual loss of $512M due to damage to distribution infrastructure caused by wildfires. By 2037, this average annual loss is expected to increase to approximately $584M or an increase of 14 percent due to climate change.
- Factoring in PG&E's EUP, despite the expected increase in risk due to climate change, average annual losses to distribution infrastructure from wildfire damage are expected to decrease by approximately $83M, a decrease of nearly 17 percent for the remaining lifetime of distribution assets in the HFTD.

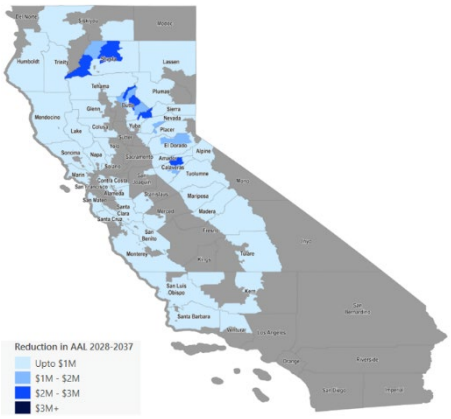

Figure 4-1: First-Average Annual Loss Reduction (First-Party Risk)

Methodology Overview

The analysis of PG&E Assets models PG&E's direct costs of replacing distribution assets due to damage caused by any wildfire events. This analysis utilizes the community risks model detailed above, specifically the result of the Marsh Monte Carlo simulation with geofencing applied. Probabilistic attribution filters are not applied to this model since the cost of PG&E asset damage does not depend on whether the simulated wildfire could be attributable to PG&E.

Approach

The approach to modeling PG&E's Assets follows these steps:

1. **Map PG&E Footprint:** Map PG&E distribution assets across its service area using data provided by PG&E.
2. **Identify AIR Fires:** Utilize Marsh CAT (natural catastrophe) modeling to identify fires within the AIR model which impact PG&E infrastructure. AIR simulation identified about 199k ignition points which impacted PG&E assets over the 10,000-year analysis period.
3. **Analyze Fire/Asset Intersections:** Marsh drew buffer zones around each ignition point, directly proportional to the "burned area" denoted by the AIR output. Marsh approximated burn scars of simulated fires, creating circular buffers around ignition points, due to a lack of burn shape information. Marsh identified all PG&E assets within each analyzed fire, assuming any asset within the fire perimeter would require 100% replacement. Per

discussions with PG&E, any simulated fire impacting a pole will result in the total loss of that pole and cost PG&E $49,048 per pole to replace.

4. **Model for Other Years:** Marsh repeated this process for each year from 2028-2037 using the respective Marsh Monte Carlo simulation for each year as well as the list of PG&E Assets for each year. Marsh assumed that in PG&E's EUP undergrounding plans, any location where PG&E indicated undergrounding results in PG&E Assets being fully replaced by underground assets that have no risk of being damaged by wildfires.

5. **Applying Climate Change:** Each simulated burn area was multiplied by its respective county's calculated 'ClimateMultiplier', representing the climate multiplier identified through Cal-Adapt (more detail on the 'ClimateMultiplier' calculation and methodology can be found in the Climate Change Methodology section).

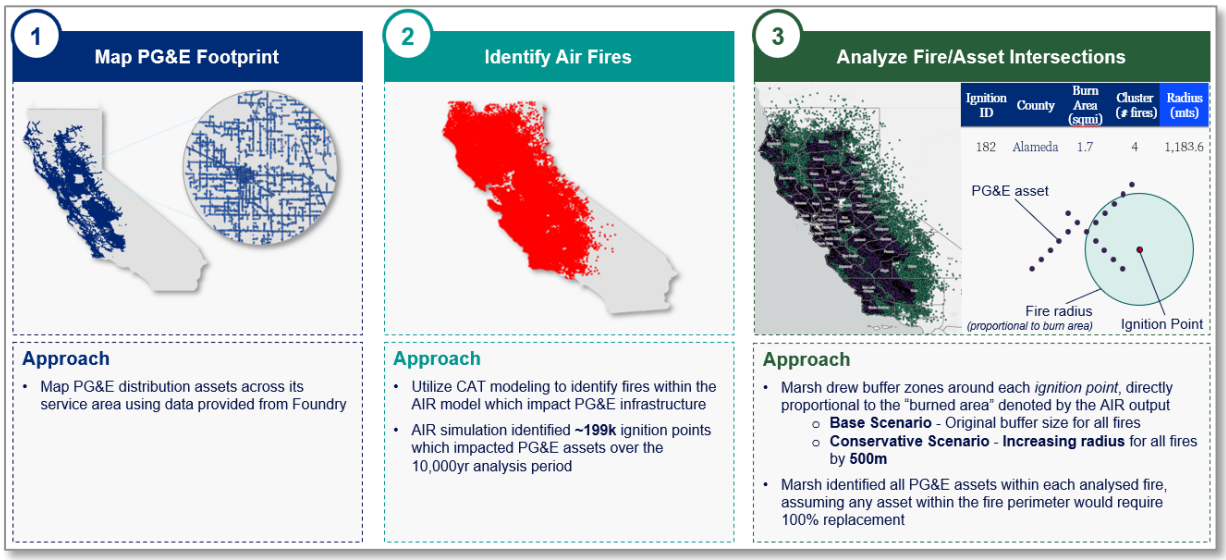

Figure 4-2: PG&E Asset Risk Analysis Methodology

Limitations

Out of ~199K AIR simulated fires, 46% of fires impacting PG&E assets form clusters, where a single "Primary" fire leads to the ignition of multiple "Associated" fires (2-10 fires per cluster).

Ignition point coordinates are provided only for the "Primary" fire in the cluster, limiting geospatial analysis as the exact ignition points for "Associated" fires are unknown.

The area burned in square miles by the largest fire in the cluster (which could be either the "Primary" or one of the "Associated" fires) is provided, but the sum of the area burnt by all fires in the cluster is unknown, further limiting geospatial analysis.

Marsh

Section 5
Homeowners Insurance Impact

Key Takeaways

- All else being equal, it is estimated that during the 10-year EUP period, the wildfire risk reduction achieved from undergrounding could facilitate a reduction in commercially available homeowners insurance premiums in PG&E's service territory of over 18 percent.

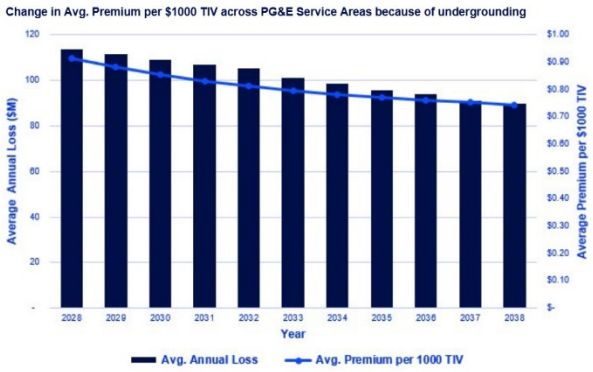

Figure 5-1: Premium Savings for Homeowners in PG&E Service Areas

Methodology Overview

The purpose of the analysis is to estimate how reductions in wildfire risk associated with PG&E's planned undergrounding program may affect homeowners insurance costs across its service territory over the 2026–2037 planning period. The analysis focuses on broad directional impacts on insurance pricing rather than predicting the premium charged to any individual homeowner or property.

At a high level, the work combines historical insurance information, property value information, and projected changes in wildfire-related loss expectations. These inputs are then used to develop an area-level view of how insurance costs may evolve if wildfire risk from utility assets declines over time.

Marsh's analysis of potential insurance premium impacts uses publicly reported historical homeowners insurance data, property value information, and projected changes in expected wildfire-related loss associated with planned undergrounding activity in its service territory. The analysis develops area-level forecasts of insurance cost measures and evaluates how reductions in wildfire risk may influence homeowners insurance premiums over time. The results are intended to provide directional insight at an aggregate level and

should not be interpreted as a prediction or guarantee of premium outcomes for any individual insurer, property, or policyholder.

Approach

The analysis was completed in a series of linked steps. First, historical homeowners insurance information was assembled for ZIP codes within and around PG&E's service territory using publicly available California Department of Insurance data. This historical information included premium levels, policy exposure, and insured property value measures for recent years.

Second, the historical ZIP code data was standardized and organized so that it could be compared consistently across years. The ZIP code information was then aligned to counties within PG&E's service territory in order to create a stable geographic view of insurance conditions over time.

Third, historical patterns in key insurance measures were used to project forward the main building blocks of future insurance cost: the number of insured risks, the insured value of property, and premium levels. These projections were prepared over the forward-looking period covered by PG&E's undergrounding plan.

Fourth, the analysis incorporated estimates of expected annual third-party wildfire loss in PG&E's service area. These loss estimates reflect the anticipated change in wildfire-related risk over time as undergrounding initiatives are implemented. In general terms, the analysis assumes that lower expected wildfire loss should support lower insurance cost pressure, all else equal.

Fifth, the analysis compared area-level insurance cost levels with area-level wildfire loss measures to evaluate how changes in expected wildfire risk may be associated with changes in insurance pricing. This step was performed at an aggregated geographic level and was intended to capture broad market relationships rather than property-specific outcomes.

Finally, the projected change in wildfire-related loss was translated into an estimated change in future homeowners insurance cost levels across PG&E service counties. The final results were summarized as changes in average premium levels and related insurance affordability indicators over the study period.

Key data inputs

The analysis relied on several categories of information:

- Historical homeowners insurance premium and exposure / policy count data from California Department of Insurance (CDI) reporting.[3]

[3] The CDI dataset Marsh used includes commercial insurance plans, specifically DO (Dwelling Owner-Occupied), DT (Dwelling Tenant-Occupied), and HO (Homeowners') type policies, and does not include state-funded insurance plans such as the FAIR Plan. Full documentation of the historical dataset from CDI: https://www.insurance.ca.gov/01-consumers/200-wrr/WildfireRiskInfoRpt.cfm

- Historical and projected measures of residential property value used to place insurance costs in context relative to insured value.
- County and ZIP code geographic mappings used to align insurance activity to PG&E's service territory.
- Projected expected annual third-party wildfire loss reductions associated with PG&E's planned undergrounding activities during the 2026–2037 period.

How the results should be interpreted

The resulting estimates are intended to show how insurance conditions may change at a portfolio or territory level if wildfire risk from PG&E assets declines over time. The results are therefore best understood as directional and area-based estimates. They are not a quote, rate filing, underwriting view, or guarantee of future premium outcomes for any insurer, policyholder, ZIP code, or county.

Insurance premiums are influenced by many factors beyond wildfire risk, including inflation, reinsurance costs, claims experience from non-wildfire perils, regulatory developments, insurer appetite, property characteristics, and broader market conditions. For that reason, the analysis isolates the effect of changing wildfire-related loss expectations within a broader and more complex insurance marketplace.

Limitations

As with any forward-looking analysis, the results are subject to uncertainty. Future insurance outcomes may differ from these estimates because of changes in market conditions, consumer behavior, insurer participation, catastrophe experience, legal and regulatory developments, macroeconomic trends, or differences between projected and actual wildfire risk reduction. The analysis should therefore be considered one decision-support input rather than a precise forecast of future market behavior.

Wildfire Benefit Cost Analysis Model White Paper

1. Overview of WBCA Model

1.1. Overview

Pacific Gas and Electric Company (PG&E) developed the Wildfire Benefit Cost Analysis (WBCA) model in accordance with SB 884 to compare the long-term costs and quantifiable benefits of Undergrounding against other mitigation alternatives including Overhead Hardening. The WBCA model provides a point-in-time comparison of mitigation alternatives at the circuit segment level and considers the lifetime costs and benefits of each mitigation.

The WBCA model quantifies the risk reduction for ignition risk, reliability risk (including Baseline Outage Risk and Outage Program Risk), and public safety risk, and calculates the lifetime costs of each mitigation, including the mitigation installation costs and lifetime operations and maintenance (O&M) costs. The primary outputs of the WBCA model are the Benefit Cost Ratios (BCR) for each mitigation, by circuit segment, compared to a baseline scenario of PG&E's system prior to the implementation of any mitigation alternatives.

The outputs of the WBCA model are intended to support mitigation selection in PG&E's General Rate Case (GRC), PG&E's Wildfire Mitigation Plan (WMP), and PG&E's Electric Undergrounding Plan (EUP).

1.2. Mitigation Alternatives and Additional Comparisons

The following mitigations are scenarios that are considered in the WBCA model calculations for each circuit segment.

- **Baseline (existing infrastructure including operational mitigations):** Represents the "as is" system state before application of any EUP mitigation alternatives.[1] This scenario incorporates EPSS and PSPS as operational mitigations for wildfire risk on the existing overhead system.
- **Undergrounding (UG) Primary Distribution Lines:** Represents the portion of line miles addressed by undergrounding within HFTD[2] areas on the circuit segment.

---

1 The WBCA evaluates risk and cost assumptions using a point-in-time representation of PG&E's distribution system that is aligned with the system configuration snapshot used in Wildfire Distribution Risk Model (WDRM) Version 4 (V4) from January 1, 2023.

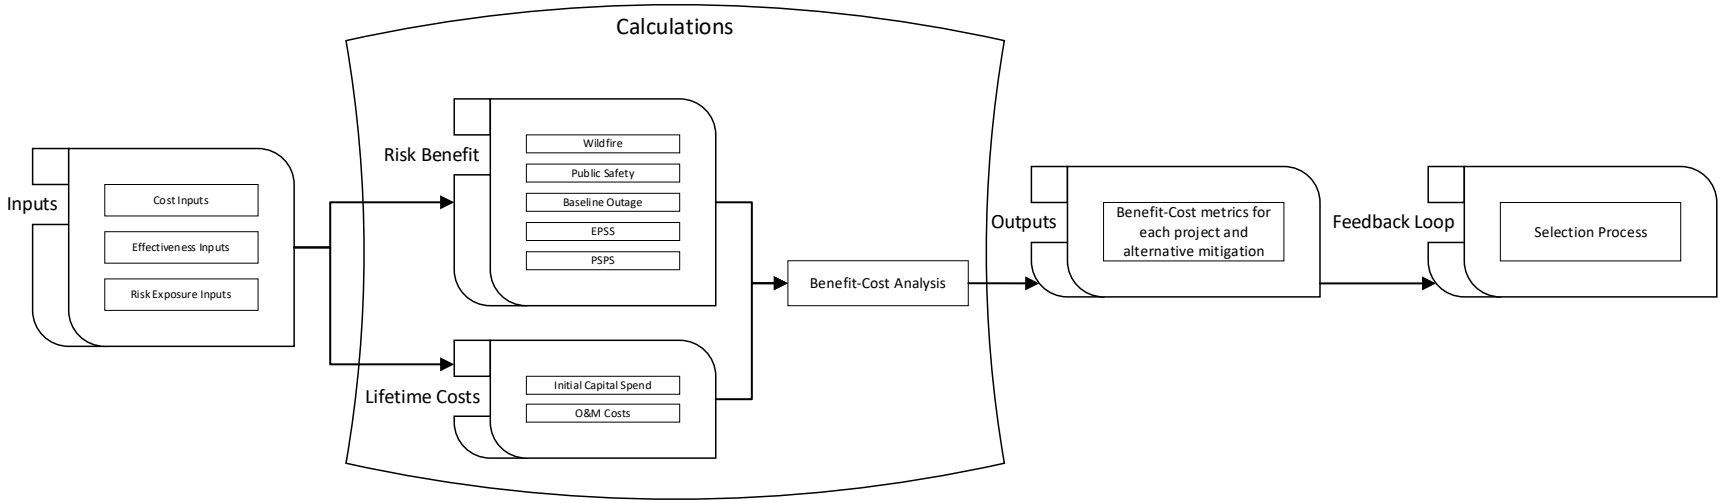

2 PG&E will scope the full extent of the HFTD *and* HFRA overhead miles within a circuit segment; however, EUP undergrounding work will be limited to HFTD areas. PG&E may file a Petition for Modification (PFM) of the CPUC's HFTD and, if that is approved, additional miles may be eligible for undergrounding.

- **Overhead Hardening (OH):** Reflects the line miles addressed by Overhead Hardening within HFTD areas on the circuit segment.
- **Remote Grid (RG) with Line Removal:** Represents the line miles addressed by Remote Grid within HFTD areas on the circuit segment, along with removal of the associated primary distribution line.
- **Hybrid Mitigations:** Assumes a percentage of the primary distribution overhead line mileage within HFTD areas on the circuit segment will be undergrounded, and remaining mileage will be addressed by either Overhead Hardening or Remote Grid with Line Removal.

1.3. WBCA Model Summary Diagram

Figure 1 provides a high-level diagram of the WBCA Model and shows how model inputs flow through the calculation process to produce outputs, including BCR results by mitigation alternative. The diagram also illustrates how the Feedback Loop informs future updates to the model by incorporating new data, assumptions, and lessons learned from implementation.

Figure 1: WBCA Model Diagram

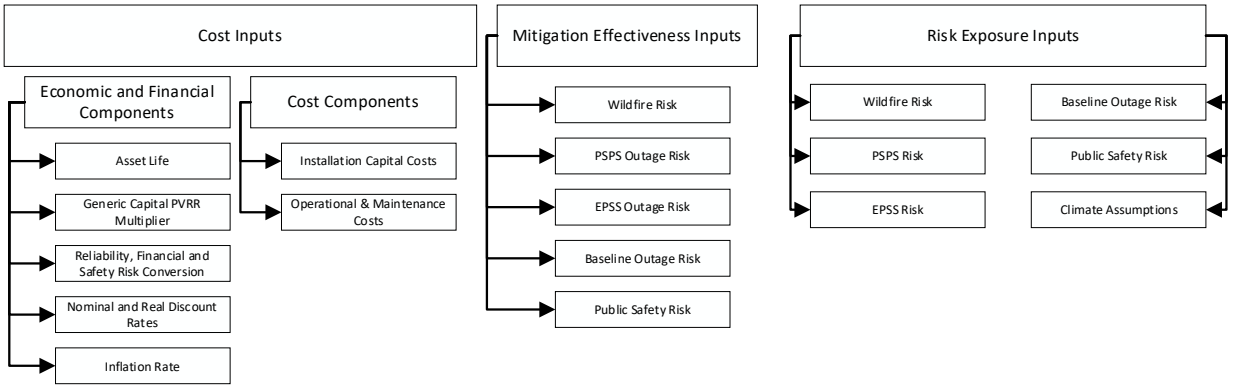

2. WBCA Model Inputs

The WBCA model was developed using three key input categories to quantify the risk reduction for ignition risk, reliability risk (including Baseline Outage Risk, EPSS and PSPS) and public safety risk, and calculate the lifetime costs of each mitigation, including the mitigation installation costs and lifetime O&M costs:

- **Cost Inputs:** Data sources that capture capital and O&M cost information used to quantify the financial components of WBCA model. These inputs include values from previously approved regulatory filings, internal analyses, and static data sources.
- **Effectiveness Inputs:** Datasets that quantify the risk reduction associated with a given mitigation alternative.
- **Risk Exposure Inputs:** Risk-modeling data and supporting datasets used to quantify pre-mitigation risk exposure, including customer interruption impacts. These inputs establish the baseline risk conditions evaluated by the WBCA and support calculation of wildfire, outage, and public safety risk-reduction benefits.

Figure 2: WBCA Model Inputs

2.1. Cost Inputs

2.1.1. Economic and Financial Components

- **Overhead, Underground, and Remote Grid Asset Life:** Asset life affects the BCR calculation by determining the duration over which both O&M costs and expected benefits are evaluated. The WBCA model uses the Overhead and Underground Asset Life adopted in CPUC Decision (D.) 23-11-069 with an adopted benefit life of 55 years for

underground assets, and 48 years for overhead assets.[3] Remote Grid asset life assumptions are calibrated to 48 years, consistent with overhead asset life assumptions.

- **Generic Capital PVRR Multiplier**: A Present Value of Revenue Requirement (PVRR) multiplier is applied to the Installation Capital Cost for each project to account for authorized returns on capital investments and discounted using After-Tax Weighted Average Cost of Capital (ATWACC). This is a financial measure, traditionally used by public utilities subject to cost-of-service regulation.

- **Cost-Benefit Approach (CBA)[4] Reliability Risk Conversion:** The CBA Reliability Risk Conversion is a Cost per Customer Minutes Interrupted (CMI) output from the Lawrence Berkeley National Laboratory Interruption Cost Estimate (ICE) Calculator to determine a standard dollar valuation of electric reliability risk for the Reliability Attribute with the main output section producing discrete results for residential and non-residential customer classes.[5] This is otherwise referred to as "value of service."

- **CBA Financial Conversion:** The CBA Financial Conversion is a Cost per Financial Impact that is a value of 1 such that the cost of a $1 financial impact is equivalent to $1.

- **CBA Safety Risk Conversion:** Calculated using Department of Transportation (DOT) guidance for the Value of a Statistical Life (VSL), adjusted for the base year considered, and California price and real wage data.[6]

- **Nominal Discount Rate:** Also referred to as the After-Tax Weighted Average Cost of Capital (ATWACC), [7] the Nominal Discount Rate is used to calculate the present value of all future costs and attributes. This rate is 7.0%

- **Inflation Rate:** Risk mitigation programs provide risk reduction benefits over multiple years; therefore, PG&E must project monetized risk values and costs over the applicable benefit period. The WBCA applies a long-term inflation assumption of 2.28%, derived from Congressional Budget Office (CBO) Consumer Price Index for All Urban Consumers (CPI-U) projections.[8] Consistent with risk-modeling practice, this inflation assumption is

---

3 Decision (D.) 23-11-069 p. 676 Table 10-E

4 D.22-12-027, Appendix A, p. A-3 defines a CBA as: "[a] decision-analysis tool for comparing the monetized Benefits of a program, or set of activities, against the costs of the program, or set of activities, to create a measurement of value."

5 2024 RAMP Section C.5.b. p. 2-12.

6 The methodology to derive the CBA Safety Risk Conversation value is consistent with the "Safety Attribute" metric outlined in the 2024 RAMP Section C.5.a. pp. 2-9 through 2-11.

7 The ATWACC used in the WBCA model is based on PG&E's cost of capital authorized in D.24-10-008.

8 PG&E's inflation assumption is based on the Congressional Budget Office (CBO), The 2025 Long-Term Budget Outlook (March 2025), which reports a CPI-U inflation projection of 2.28% for 2054.

used to escalate future costs and monetized risk values and is applied throughout the model on a consistent basis.

- **Real Discount Rate:** The Real Discount Rate is used to calculate the net present value of risk reduction benefits and the lifetime costs for each mitigation considered. A real discount rate of 4.61% is calculated using the Fisher equation, applying the nominal discount rate and inflation rate.

2.1.2. Cost Components

- **Installation Capital Costs:** Installation capital cost assumptions are the assumed capital costs for installation in 2028.
    - Baseline scenario assumes no installation capital costs.
    - Installation costs for the Undergrounding mitigation scenario are derived from planning-level cost estimates used in Screen 2 benefit-cost evaluations. These cost assumptions are informed by historical undergrounding project experience and vary based on project feasibility characteristics such as hard rock conditions, terrain gradient, and water crossings. As projects advance through Screen 3 and beyond, additional scope and engineering information becomes available, and cost estimates are further refined.
    - The Remote Grid mitigation scenario in Screen 2 assumes standard installation costs on a per-customer basis. These costs are subsequently refined as project scope, customer impacts, and implementation requirements are further developed through Screen 3 and subsequent stages of project evaluation. Some Alternative Mitigation 2 Remote Grid projects will have a total cost zero because remote grid costs are based on the number of customers located on the circuit segment. For segments with no customers, there are no remote grid costs to assign, resulting in a total project cost of zero.
    - The OH mitigation scenario in Screen 2 assumes standard installation costs on a per-mile basis. These costs are subsequently refined as project scope, customer impacts, and implementation requirements are further developed through Screen 3 and subsequent stages of project evaluation.
- **O&M Costs:** O&M costs are estimated forecast costs to operate and maintain an asset over its lifetime. O&M costs are evaluated across multiple categories, each with distinct data sources, assumptions, and cost drivers. O&M costs are calculated at the circuit-segment level for the baseline and each mitigation type. The incremental O&M costs associated with each mitigation alternative, relative to the baseline scenario, are then incorporated into the cost component of the WBCA benefit-cost analysis for each project.
    - PG&E Subject Matter Experts (SMEs) reviewed each O&M cost category to identify the most appropriate data sources and forecasting assumptions. Depending on the cost category, O&M assumptions may be based on adopted

GRC forecasts, historical spending patterns, or other program-specific cost analyses.

- PG&E evaluated each O&M cost category to determine how costs would change under the Baseline, Undergrounding, Remote Grid, and OH mitigation scenarios. O&M cost assumptions were developed for each scenario based on the costs expected to be incurred over the asset life and therefore vary by mitigation type.
- For each O&M cost category, the project spend is divided by line miles to derive the unit cost per mile, with the exception of EPSS and Public Safety Power Shutoffs (PSPS) O&M costs, as those costs are represented as a cost per CMI.

Table 1 below summarizes the historical datasets, forecasting assumptions, and calculation methods used for each category, including applicable GRC forecasts, historical expenditures, filtering criteria, and key cost drivers such as unit costs, line mileage, and event assumptions:

Table 1: O&M Cost Categories, Data Sources, and Forecasting Assumptions

Cost Category	Basis for Analysis	Inclusion/Exclusion Filters
Patrols & Inspections	**Overhead** • 4-year average utilizing the 2023 GRC adopted forecast, with escalation, for years 2023 through 2026. • The average unit cost for MATs BFA, BFB, BFC, BFG, and GAA uses the BPD proposed unit cost from the 2024 Q1 Electric Cost Book. • The average unit cost for MATs BFH, BFJ, BFL, BFM, and BFO is based on the 2023 GRC adopted forecast with escalation, using the average costs for 2023 through 2026 divided by the 2023 Primary Overhead Distribution line miles. MAT BF# unit cost uses 2023 actuals from Business Finance. **Underground** • Analysis uses the 2023 GRC adopted forecast, with escalation, for years 2023 through 2026.	**Overhead** • **Includes:** 07A, BFA, BFB, BFC, BFG, BFH, BFJ, BFL, BFM, BFO, GAA, GAC, GAI, and BF#, representing non-PTT pole inspections, number of miles, number of poles tested and treated, and number of poles. • **Excludes:** 07A and GAI are excluded because these MAT codes are not directly aligned to the unit-based patrol and inspection cost drivers (e.g., miles, poles inspected, poles treated) used in the WBCA analysis. As a result, they were removed to ensure only comparable and scalable inspection activities are included. **Underground** • **Includes:** BF4, BFD, and BFE, which are specific to O&M costs for patrols and inspections. • **Excludes:** NA
Maintenance & Repair	• 4-year average utilizing the 2023 GRC adopted forecast, with escalation, for years 2023 through 2026.	• **Includes:** MWCs 07, 08, 2A, 56, KA, KB, and GA, which are specific to O&M costs for maintenance and repair activities. • **Excludes:** NA
Supervision & Engineering	• 4-year average utilizing the 2023 GRC adopted forecast, with escalation, for years 2023 through 2026. • The average unit cost for the engineering MAT codes selected was calculated using the average of the 2023 GRC adopted forecast for years 2023 through 2026.	• **Includes**: MAT codes FZA, FZB, FZC, FZD, and FZE, which are used for engineering and are applied on a unit cost per mile basis. • **Excludes**: NA
PSPS	• 4-year average utilizing the 2023 GRC adopted forecast, with escalation, for years 2023 through 2026. • The analysis uses the 2023 GRC adopted forecast because, during the 2023 GRC filing, the PSPS program was relatively new and reflected two full PSPS seasons in 2019 and 2020.	• **Includes**: MAT AB6, limited to the work category “Public Safety Power Shutoff - PSPS Event (Distribution),” representing event-driven PSPS execution costs. • **Excludes**: All other activities within AB6 that would not be directly impacted by undergrounding, including fixed PSPS program

Cost Category	Basis for Analysis	Inclusion/Exclusion Filters
	• The PSPS event forecast assumes three PSPS events, plus one additional potential or borderline event per year, based on a 10-year historical weather analysis. • Cost per event is based on the average cost per event over 2019 and 2020.	costs and activities not directly related to severe weather that can lead to PSPS execution.
Major Outage & Emergency	• 5-year average utilizing 2020 through 2024 historical costs. • The analysis uses recorded data for 2020 through 2024 because the major emergency forecast is driven by a 5-year average of actual costs.	• **Includes**: MATs 95A, 95B, 95F, IFB, IFA, IFC, and IFF, which are specific to O&M costs for major outage and emergency activities. • **Excludes**: Major fire rebuild expenses (MAT 95F) are not included in the cost-per-mile calculations.
Routine Outage & Emergency	• 2024 historical costs. • A 2 percent growth factor is applied to the 2024 recorded data and then divided by overhead miles to develop a cost per mile by division. • This approach was used because it provides a better estimate of future routine spend and reflects year-over-year growth in both units and dollars that was not captured in the 2023 GRC forecast at the time it was submitted.	• **Includes:** MATs 17B, 17C, 17D, 17P, BHD, BHG, BHH, BHB, and BHC, representing Routine Emergency response spend used in the WBCA analysis. • **Excludes:** BHE is excluded because it is already captured in overhead-related activities and including it would result in double counting. • **Additional Context:** MAT BHE is part of the overall Routine Emergency program spend but was removed from the WBCA cost-per-mile calculations to avoid duplication.

EPSS	• 2024 historical costs.
	• The analysis uses 2024 historical actuals to ground the cost estimates in observed data rather than forecasts, support a more accurate and conservative basis for evaluating undergrounding benefits, align with outage risk modeling outputs, and support cost-per-CMI calculations using actual spending tied to MAT codes directly impacted by undergrounding.
		• **Includes:** 09B, 3US, 49H, 49T, 49X, BHE, IG# utilized for EPSS CMI analysis.
		• **Excludes:** All other EPSS-related MAT codes that are not directly impacted by undergrounding are excluded from avoided cost consideration.
		• **Additional Details:**
		  • The EPSS Cost per Customer Minute Interrupted (CMI) analysis utilizes MAT codes 09B, 3US, 49H, 49T, 49X, BHE, IG#.
		  • All other EPSS-related MAT codes include activities not directly impacted by undergrounding and are therefore excluded.
		  • 09B – Dist. Sub IPAC Replacement: Supports EPSS and DCD functionality by replacing outdated relays.

Cost Category	Basis for Analysis	Inclusion/Exclusion Filters
		• 3US – DCD Radio Comms: Enables Downed Conductor Detection (DCD); added since GRC 2023. • 49H / 49T / 49X – ED Reliability: Targets poor-performing circuits; 49X includes fault indicators and sectionalization. • BHE – Outage Response: Covers patrols and response efforts during EPSS events. • IG# – Helicopter Standby: Supports aerial patrols for EPSS reliability. • **Additional Context:** Per Decision (D.) 23-11-069, the Commission adopted PG&E's 2023 expense forecast for EPSS at $151.129 million (p.317). The EPSS costs reflected in our workbooks represent an approximate 40% portion of the total EPSS budget that was approved in the 2023 GRC. This demonstrates that the EPSS related costs included here are relatively small subset of the overall authorized EPSS funding.
Vegetation Management	• Vegetation Management O&M data used in the analysis consists of the 2027 GRC forecasted cost, in consideration of PG&E's focus on reducing vegetation costs for ratepayers. • To address outliers and gaps in the recorded Vegetation Management O&M data, a linear regression analysis was applied using a tree tag to tree strike ratio. The regression model is applied only to circuit segments that are above or below one standard deviation from the mean tree tag to tree strike ratio. This analysis yielded a circuit-segment per-mile Vegetation Management O&M unit cost, rather than applying a uniform distribution of Vegetation Management O&M cost across all circuit-segments. • In response to Data Request CalAdvocates-PGE-NonCase-MMH-01162026-ICE_and_VM, PG&E provided the linear regression analysis workbook with the underlying assumptions and basis for the analysis. Please refer to the previously provided attachment DRU16828_System Hardening_DR_CPUC_D001Atch04.xlsx for additional information.	• **Includes:** HN and IG, which are Vegetation Management MAT/MWC codes. • **Excludes:** NA

Cost Category	Basis for Analysis	Inclusion/Exclusion Filters
Estimated External Fire Rebuild	• Forecasted costs associated with repairing and replacing distribution assets damaged by external wildfires (i.e., not caused by PG&E utility equipment or operations). • Costs are informed by a wildfire risk assessment that evaluates the expected frequency of wildfire impacts to distribution assets within Tier 2 and Tier 3 High Fire Threat Districts. • The analysis estimates expected annual rebuild costs based on asset exposure, replacement costs, and climate-adjusted wildfire risk forecasts, and provides a forward-looking estimate of wildfire-related rebuild expenditures.	• **Includes:** See Basis for Analysis. • **Excludes:** Historical fire rebuild costs are excluded in lieu of these estimates.

2.2. Mitigation Effectiveness Inputs

The descriptions below provide a high-level overview of the datasets, analyses, and assumptions used to estimate mitigation effectiveness for each risk category evaluated in the WBCA model. Additional methodology details, supporting calculations, source data, and derivation of mitigation effectiveness values are documented in PG&E's Attach. B, WP001 (Mitigation Effectiveness Analysis).

- **Mitigation Effectiveness Sources:**
    - **Wildfire Mitigation Effectiveness:** The WBCA model calculates wildfire mitigation effectiveness at the circuit-segment level using results from PG&E's Wildfire Mitigation Effectiveness Analysis. Historical outage events are categorized based on factors such as outage cause, equipment involved, and equipment condition. Subject matter experts evaluate how effectively each mitigation alternative would prevent ignition across these outage scenarios, and the resulting effectiveness values are mapped to the ignition-likelihood drivers used in the Wildfire Distribution Risk Model (WDRM). Circuit-segment-specific wildfire mitigation effectiveness is then calculated by weighting these effectiveness values according to the relative contribution of each ignition driver to the segment's overall ignition risk.
    - **PSPS Outage Risk:** PSPS mitigation effectiveness is based on whether a mitigation alternative removes the overhead infrastructure exposure that gives rise to PSPS-related outage risk. Mitigations that eliminate exposure of overhead assets to weather-driven de-energization conditions, such as undergrounding and line removal, also eliminate the PSPS-related outage risk associated with those facilities. Overhead mitigations which leave those exposure pathways in place are assumed to provide no PSPS risk reduction.
    - **EPSS Outage Risk:** EPSS mitigation effectiveness is based on whether a mitigation alternative removes or reduces the overhead infrastructure exposure that gives rise to EPSS-related outage risk. This exposure is associated with weather-related and other external drivers that can result in EPSS-triggered outages. Mitigations that eliminate all overhead asset exposure, such as undergrounding and line removal, are assumed to eliminate the EPSS-related outage risk associated with those facilities. Overhead hardening with covered conductor is assumed to reduce but not eliminate EPSS-related risk by reducing the frequency of faults that would result in EPSS outages.
    - **Baseline Outage Risk:** Baseline Outage Risk effectiveness measures the extent to which a mitigation reduces non-PSPS and non-EPSS outage impacts. For undergrounding, effectiveness is estimated empirically by comparing historical reliability performance of underground and overhead systems using normalized outage-duration metrics. For overhead mitigation alternatives, effectiveness is estimated through analysis of historical outage profiles and SME assessment of how frequently the mitigation would prevent or reduce outage-causing events.

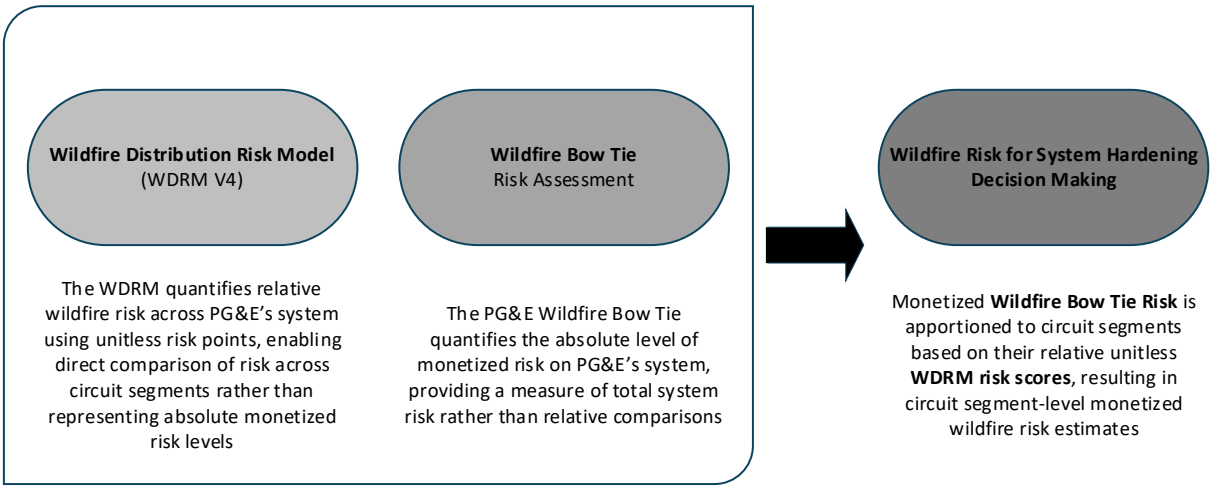

- **Public Safety (PCEEE) Mitigation Effectiveness:** The estimated Third-Party/Public Safety Mitigation Effectiveness of undergrounding is evaluated by comparing historic rates of Equivalent Fatalities (EFAT) attributed to Distribution Overhead and Distribution Underground assets normalized by their respective mileages. For overhead mitigations which do not materially change public exposure to energized equipment, no reduction in PCEEE risk is assumed.

2.3. Risk Exposure Inputs

The primary risk inputs are: Wildfire Risk, PSPS Risk, EPSS Risk, Baseline Outage Risk and Public Safety (PCEEE) Risk. These inputs are evaluated separately because they represent different types of risk, rely on different upstream datasets, and are mitigated in different ways. The WBCA then combines the monetized risk reduction from each category to estimate the total lifetime benefit of each mitigation alternative.

- **Wildfire Risk:** Wildfire risk represents the potential for overhead distribution assets to cause an ignition resulting in wildfire consequences. WBCA estimates wildfire exposure using two primary inputs: the Wildfire Distribution Risk Model (WDRM) and PG&E's Enterprise Wildfire Bowtie analysis. The WDRM provides circuit-segment-level estimates of relative ignition risk, while the Enterprise Bowtie provides the system-level monetized wildfire risk used in PG&E's enterprise risk framework. Consistent with the WBCA baseline assumption, the incorporated Bowtie output reflects residual wildfire risk after accounting for the system-level risk reduction provided by PSPS and EPSS as existing operational mitigations. WBCA allocates this monetized post-PSPS-post-EPSS wildfire risk across circuit segments based on their relative WDRM risk scores to derive circuit-segment-level wildfire exposure values. Figure 3 below summarizes how these datasets are combined to estimate circuit-segment-level wildfire exposure:

Figure 3. Calculation of Circuit-Segment-Level Wildfire Risk Using WDRM and Enterprise Bowtie Risk Inputs

- **PSPS Risk:** PSPS risk represents the customer reliability and safety impacts associated with Public Safety Power Shutoff events. WBCA evaluates PSPS risk separately to capture the benefits of mitigation alternatives that reduce the need for PSPS activations. Circuit-segment-level PSPS risk is derived from the Outage Program Risk Model (OPRM), which quantifies the reliability impacts of PSPS events, together with indirect safety risk from PG&E's Enterprise PSPS Bowtie analysis. The indirect safety risk is allocated to circuit segments based on each segment's share of total system PSPS risk.
- **EPSS Risk:** EPSS Risk represents the customer reliability and safety impacts associated with Enhanced Powerline Safety Settings. WBCA evaluates EPSS risk separately to capture the benefits of mitigation alternatives that reduce EPSS outages. Circuit-segment-level EPSS risk is also derived from the OPRM, which quantifies the reliability impacts of EPSS-related outages, together with indirect safety risk from PG&E's Enterprise EPSS Bowtie analysis. The indirect safety risk is allocated to circuit segments based on each segment's share of total system EPSS risk.
- **Baseline Outage Risk:** Baseline Outage risk represents reliability risk from sustained outages that are not attributable to EPSS or PSPS. In other words, it captures the outage risk expected during normal operations, excluding customer interruptions caused by wildfire mitigation outage programs. Circuit-segment-level Baseline Outage risk is also derived from the OPRM, which quantifies the reliability impacts of these outages, together with indirect safety risk from PG&E's Enterprise DOVHD Bowtie analysis. The indirect safety risk is allocated to circuit segments based on each segment's share of Baseline Outage CMI.
- **Public Safety Risk:** Public safety risk represents non-wildfire safety risk associated with overhead electric distribution assets. This includes risks such as public contact with energized electrical equipment, downed energized conductors, and other non-wildfire

safety events involving distribution infrastructure. WBCA evaluates public safety risk separately because it captures direct safety consequences that are distinct from wildfire and outage-related risks. Circuit-segment-level public safety exposure is derived from PG&E's PCEEE Enterprise Bowtie analysis, which provides the system-level monetized public safety risk. This risk is allocated across primary overhead distribution line miles to estimate circuit-segment-level public safety exposure.

- **Climate Assumptions:** Because mitigation benefits are evaluated over multiple decades, the WBCA applies climate multipliers to reflect projected changes in risk exposure over time. These multipliers are based on two key variables that capture the effects of changing weather conditions on wildfire risk and equipment performance:
    - *Fire Weather Index (FWI) Analysis:* The FWI variable measures the annual number of days per circuit segment that exceeds the historical 95th percentile FWI value, calculated using baseline data from 1995-2014. The FWI is a generalized measure of fire potential that incorporates both fuel aridity and fire weather conditions, regardless of fuel type or abundance. It is calculated using daily maximum temperature, minimum relative humidity, average wind speed, and precipitation. Changes in the frequency of high-FWI days impact the probability that an ignition occurs during Red Flag Warning (RFW) conditions. Since ignitions associated with RFW conditions have higher per-event consequences than non-RFW ignitions, a risk multiplier for RFW outcomes is calculated at the circuit segment level. This multiplier scales proportionally with increases in annual days exceeding the historical 95th percentile Fire Weather Index.[9]
    - *Heat Day Analysis:* Equipment failure rates are modeled to increase proportionally with the frequency of continued heat events. These events are defined as periods of three consecutive days exceeding 92°F where both daily highs and lows surpass their respective 10-year averages. A heat-based equipment-failure frequency multiplier is calculated at the circuit segment level to capture climate-driven changes in sustained heat exposure.

Application of Climate Multipliers: The multipliers are applied to the relevant risk categories. The FWI multiplier is applied to Wildfire, PSPS and EPSS risks, and the heat multiplier is applied to Wildfire, EPSS,[10] and Baseline Outage risks, ensuring that

---

9 Climate projections are derived from the ensemble average of wildfire risk simulations driven by eight downscaled Global Climate Models under the SSP3-7.0 scenario. Future exceedance counts are valuated using projected climate conditions averaged over 20-year windows centered on 2030, 2050, and 2080.

10 Note that the following equipment-based outages are excluded from the analysis for EPSS: (a) transformer outages because they occur on secondary conductors and cannot be detected by EPSS-enabled devices, (b) switch outages because they cannot be triggered by EPSS-enabled devices, and (c) forced outages because they occur due to human decisions rather than being automatically triggered by EPSS-enabled devices.

climate impacts are appropriately reflected across all relevant risk categories. The WBCA applies the corresponding climate multipliers to these risk categories as reflected in the risk-specific exposure calculations. PG&E develops annual climate factors for each year of the WBCA benefit period and applies the applicable climate factor in the risk calculations starting in the baseline year. These annual climate factors are used to reflect projected changes in wildfire and outage risk over the life of the evaluated mitigation alternative. Public safety risk is not climate-adjusted because the non-wildfire public safety events evaluated in the WBCA, such as contact with live downed wires, are not expected to be materially affected by climate change.

3. Calculations

PG&E uses Benefit-Cost Ratios (BCRs) to evaluate the long-term benefits of a project. To derive BCR, the following metrics must be calculated:[11]

- **Lifetime Risk Benefit**: Wildfire, Public Safety, Baseline Outage, EPSS, PSPS
- **Lifetime Costs** of the Project including installation capital costs and incremental O&M costs relative to the baseline.

3.1. Risk Benefit Calculations

Risk-reduction benefit calculations quantify the estimated reduction in monetized risk associated with implementation of a mitigation alternative on a circuit segment. The WBCA evaluates five categories of risk-reduction benefits: Wildfire, Public Safety, Baseline Outage, EPSS, and PSPS. Each category is assessed separately because it relies on different underlying datasets, risk drivers, and mitigation effectiveness assumptions.

For each risk category, risk-reduction benefit is calculated as the product of risk exposure and mitigation effectiveness. Risk exposure represents the monetized pre-mitigation risk attributed to a circuit segment, and mitigation effectiveness represents the percentage reduction in that risk resulting from implementation of the mitigation alternative. Circuit-segment-level risk is derived by combining circuit-segment data and system-level monetized risk estimates from PG&E's Enterprise Risk Bowties. Risk exposure values are escalated to the adopted baseline year using the applicable climate and/or inflation assumptions before calculating lifetime benefits. The following sections describe the calculation methodology for each risk category.

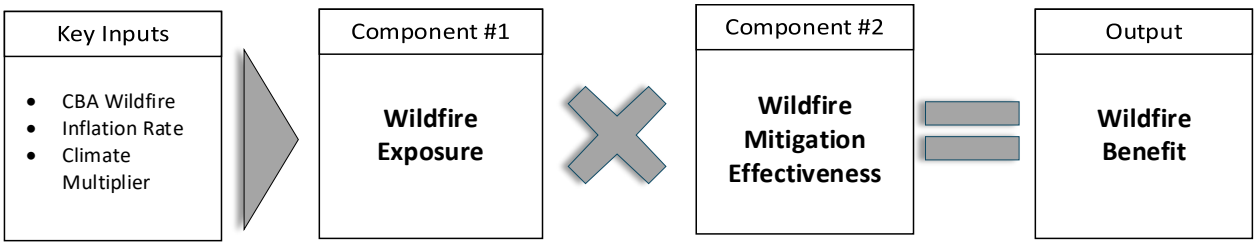

3.1.1. Wildfire Benefit

Overview: Wildfire benefit quantifies the wildfire risk reduction associated with each circuit segment when a particular mitigation is implemented. PG&E calculates Wildfire Benefit as the product of two components: Wildfire Exposure ($millions) and Wildfire Mitigation Effectiveness.

---

[11] BCR is calculated in accordance with the RDF (R.20-07-013); Decision (D.)22-12-027.

Figure 4: Wildfire Benefit Calculation

Where:

Component	Description / Formula
Wildfire Exposure ($M)	(Current Year Post-PSPS-Post-EPSS Wildfire Exposure ($M)) × (Climate Multiplier) × (1 + Inflation Rate)$^{(Escalated)}$ Where: Current Year Post-PSPS-Post-EPSS Wildfire Exposure ($M) = WDRM Risk Points × Total CBA per Unit for Wildfire And: Total CBA per Unit for Wildfire = (Enterprise WLDFR Post-PSPS-Post-EPSS Risk ($M)) ÷ (WDRM Total Risk Points)
Wildfire Mitigation Effectiveness	Input from PG&E's Mitigation Effectiveness analysis. Additional methodology details, supporting calculations, and effectiveness derivations are documented in PG&E's WP001 Mitigation Effectiveness White Paper.

Wildfire Exposure is calculated using WDRM risk scores as the basis for allocating system-level monetized wildfire risk to circuit segments. Total monetized Post-PSPS-Post-EPSS wildfire risk, as evaluated through PG&E's Enterprise Wildfire Risk Model, is divided by total system-wide WDRM risk points to calculate the wildfire CBA per WDRM risk point. Each circuit segment's WDRM risk points are then multiplied by this unitized value to estimate current-year Post-PSPS-Post-EPSS wildfire exposure.

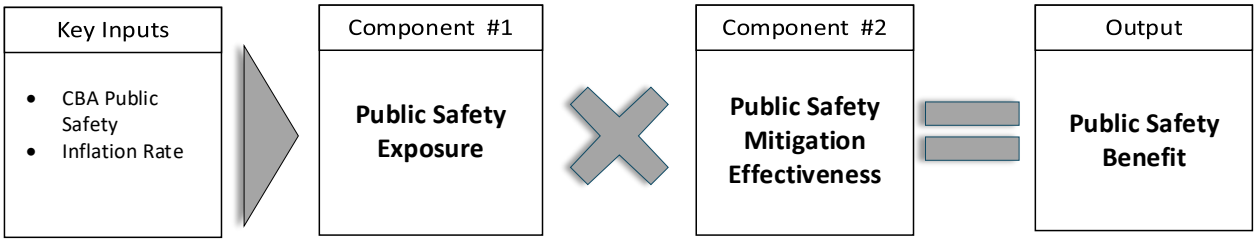

The current-year risk exposure value is then adjusted using a climate multiplier, which reflects the estimated impact of projected climate conditions as of the WBCA baseline year used for benefit-cost calculations. The resulting exposure value is then escalated using the applicable inflation assumption. Lifetime wildfire exposure is subsequently calculated by applying the applicable climate-adjusted present value factor over the benefit period.

3.1.2. Public Safety Benefit

Overview: Public Safety Benefit quantifies the non-wildfire public safety risk reduction associated with each circuit segment when a particular mitigation is implemented. Public safety (PCEEE) risk includes non-wildfire safety risks involving overhead electric distribution assets,

such as public contact with energized equipment, downed energized conductors, and similar events. PG&E calculates Public Safety Benefit as the product of two components: Public Safety Exposure and Public Safety Mitigation Effectiveness.

Figure 5: Public Safety Benefit Calculation

Where:

Component	Description / Formula
Public Safety Exposure ($M)	$(\text{Primary Overhead Miles}) \times (\text{Public Safety CBA per Unit}) \times (1 + \text{Inflation Rate})^{(\text{escalated})}$ Where: Public Safety CBA per Unit = (Enterprise Electric Distribution Overhead PCEEE Risk ($M)) ÷ (Electric Distribution Overhead Circuit Line Miles) And: PCEEE refers to the Public Contact with Intact Energized Electrical Equipment Enterprise Risk Model.
Public Safety Mitigation Effectiveness	Input from PG&E's Mitigation Effectiveness analysis. Additional methodology details, supporting calculations, and effectiveness derivations are documented in PG&E's WP001 Mitigation Effectiveness White Paper.

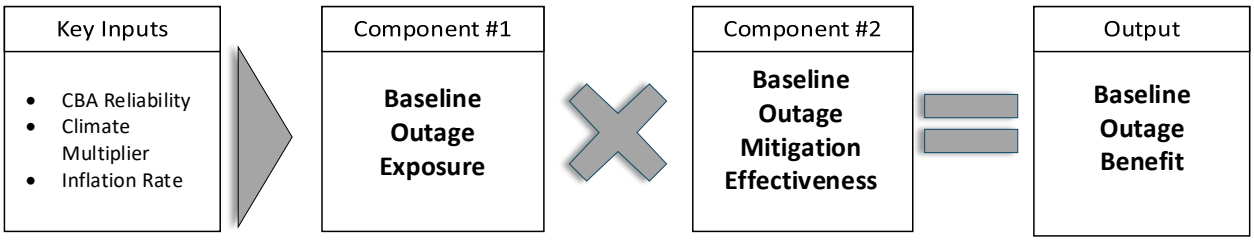

Public Safety Exposure is calculated by allocating PG&E's system-level non-wildfire public safety risk to circuit segments based on primary overhead distribution line miles. The system-level public safety risk value is derived from PG&E's PCEEE Bowtie Model and divided by total primary overhead circuit line miles to calculate the public safety risk value per overhead mile. Each circuit segment's primary overhead mileage is then multiplied by this unitized value to estimate current-year public safety exposure.

The current-year exposure value is adjusted to the adopted baseline year using the applicable inflation factor. Public Safety Mitigation Effectiveness is an input from PG&E's Mitigation Effectiveness analysis and represents the estimated percentage reduction in non-wildfire public safety risk for the applicable mitigation alternative. Additional methodology details are documented in PG&E's Mitigation Effectiveness white paper.

3.1.3. Baseline Outage Benefit

Overview: Baseline Outage Benefit quantifies the reduction in monetized baseline outage risk associated with each circuit segment when a particular mitigation is implemented. Baseline outage risk includes non-PSPS and non-EPSS customer interruptions occurring during normal system operations and is measured using customer minutes interrupted (CMI). PG&E calculates Baseline Outage Benefit as the product of two components: Baseline Outage Exposure and Baseline Outage Mitigation Effectiveness.

Figure 6: Baseline Outage Benefit Calculation

Where:

Component	Description / Formula
Baseline Outage Risk Exposure ($M)	((Baseline Outage Risk) + (Baseline Outage Annual CMI) × (DOVHD Indirect Safety CBA per Unit)) × (Climate Multiplier) × (1 + Inflation Rate)$^{(escalated)}$ Where: DOVHD Indirect Safety CBA per Unit = (Enterprise DOVHD Indirect Safety Risk ($M)) ÷ (Total Distribution Baseline Outage CMI) And: DOVHD refers to the Failure of Electric Distribution Overhead Assets Enterprise Risk Model.
Baseline Outage Mitigation Effectiveness	Input from PG&E's Mitigation Effectiveness analysis. Additional methodology details, supporting calculations, and effectiveness derivations are documented in PG&E's WP001 Mitigation Effectiveness White Paper.

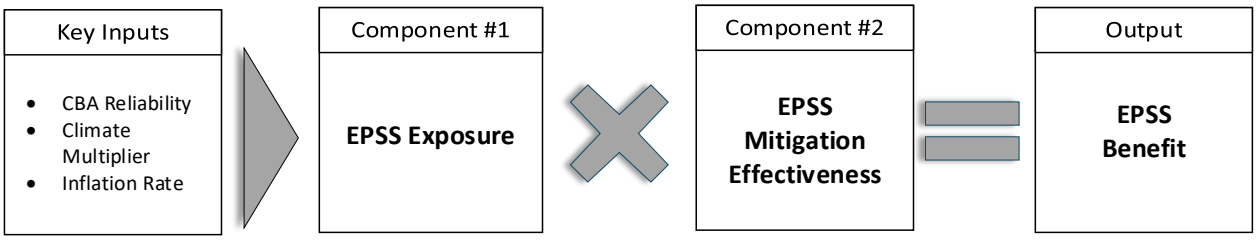

Baseline Outage Exposure is calculated by combining the monetized baseline outage risk and the indirect safety risk associated with customer interruptions. Baseline outage risk reflects the dollarized reliability impact of non-PSPS and non-EPSS outages. The indirect safety component is derived from PG&E's DOVHD Bowtie Model and allocated across total distribution baseline outage CMI to calculate the reliability indirect safety cost-benefit value per CMI. Each circuit segment's baseline outage CMI is then multiplied by this unitized value and added to the dollarized baseline outage risk to estimate current-year Baseline Outage risk exposure.

The current-year exposure value is adjusted to the adopted baseline year using the applicable inflation factor and, where applicable, the corresponding climate-adjusted present-value factor over the benefit period. Baseline Outage Mitigation Effectiveness is an input from PG&E's Mitigation Effectiveness analysis and represents the estimated percentage reduction in baseline outage risk for the applicable mitigation alternative. Additional methodology details are documented in PG&E's Mitigation Effectiveness white paper.

3.1.4. EPSS Benefit

Overview: EPSS Benefit quantifies the change in monetized outage risk associated with Enhanced Powerline Safety Settings when a mitigation alternative either introduces, reduces, or removes the overhead exposure that gives rise to EPSS-related interruptions. EPSS risk reflects customer interruptions caused by EPSS operations and is measured using customer minutes interrupted (CMI). These interruption impacts are converted to a monetized reliability-risk value using the CBA Reliability Risk Conversion (i.e., value of service) described in Section 2.1.1 and incorporated within the OPRM outage-risk outputs used by the WBCA. PG&E calculates EPSS Benefit as the product of two components: EPSS Exposure and EPSS Mitigation Effectiveness.

Figure 7: EPSS Benefit Calculation

Where:

Component	Description / Formula
EPSS Exposure ($M)	((EPSS Outage Risk) × (1 + EPSS Indirect Safety Multiplier)) × (Climate Multiplier) × (1 + Inflation Rate)$^{(escalated)}$ Where: EPSS Indirect Safety Multiplier = (Enterprise EPSS Indirect Safety Risk ($M)) ÷ (Total System EPSS Outage Risk ($M))
EPSS Mitigation Effectiveness	Input from PG&E's Mitigation Effectiveness analysis. Additional methodology details, supporting calculations, and effectiveness derivations are documented in PG&E's WP001 Mitigation Effectiveness White Paper.

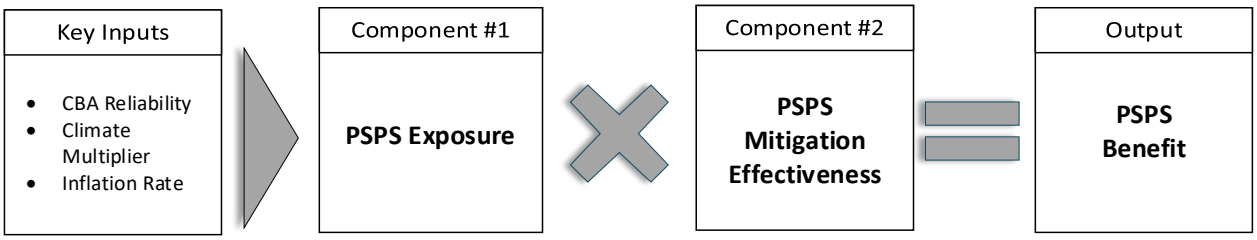

EPSS Exposure is calculated by combining the monetized EPSS outage risk and the indirect safety risk associated with EPSS-related customer interruptions. EPSS outage risk reflects the dollarized reliability impact of customer interruptions caused by EPSS operations. The indirect safety component is derived from PG&E's Enterprise EPSS Bowtie analysis and allocated across total system EPSS risk to calculate the EPSS indirect safety risk component. These components are combined to estimate current-year EPSS exposure for alternatives where EPSS-related impacts are evaluated.

The current-year exposure value is adjusted to the adopted baseline year using the applicable climate multiplier and inflation factor. Lifetime EPSS exposure is then calculated by applying the applicable climate-adjusted present-value factor over the benefit period. EPSS Mitigation Effectiveness is an input from PG&E's Mitigation Effectiveness analysis and represents the estimated percentage change in EPSS-related outage risk for the applicable mitigation alternative. Additional methodology details are documented in PG&E's Mitigation Effectiveness white paper.

3.1.5. PSPS Benefit

Overview: PSPS Benefit quantifies the reduction in monetized outage risk associated with Public Safety Power Shutoff events when a mitigation alternative removes the overhead exposure that gives rise to PSPS-related interruptions. PSPS risk reflects customer interruptions caused by PSPS activations and is measured using customer minutes interrupted (CMI), which are converted to a monetized reliability-risk value using the CBA Reliability Risk Conversion (i.e., value of service). As shown in Figure 8 below, PG&E calculates PSPS Benefit as the product of two components: PSPS Exposure and PSPS Mitigation Effectiveness.

Figure 8: PSPS Benefit Calculation

Where:

Component	Description / Formula
PSPS Exposure ($M)	((PSPS Outage Risk)[12] × (1 + PSPS Indirect Safety Multiplier)) × (Climate Multiplier) × (1 + Inflation Rate)$^{(escalated)}$ Where: PSPS Indirect Safety Multiplier = (Enterprise PSPS Indirect Safety Risk ($M)) ÷ (Total System PSPS Outage Risk ($M))
PSPS Mitigation Effectiveness	Input from PG&E's Mitigation Effectiveness analysis. Additional methodology details, supporting calculations, and effectiveness derivations are documented in PG&E's WP001 Mitigation Effectiveness White Paper.

PSPS Exposure is calculated by combining the monetized PSPS outage risk and the indirect safety risk associated with PSPS-related customer interruptions. PSPS outage risk reflects the dollarized reliability impact of customer interruptions caused by PSPS activations. The indirect safety component is derived from PG&E's Enterprise PSPS Bowtie analysis and allocated across total system PSPS risk to calculate the PSPS indirect safety risk component. These components are combined to estimate current-year PSPS exposure.

The current-year exposure value is adjusted to the adopted baseline year using the applicable climate multiplier and inflation factor. Lifetime PSPS exposure is then calculated by applying the applicable climate-adjusted present-value factor over the benefit period. PSPS Mitigation Effectiveness is an input from PG&E's Mitigation Effectiveness analysis and represents the estimated percentage reduction in PSPS-related outage risk for the applicable mitigation alternative. Mitigation alternatives that remove overhead facilities from PSPS exposure, such as Undergrounding and Remote Grid with line removal, are credited with reducing PSPS-related outage risk. Overhead mitigation alternatives that leave the relevant exposure pathway in place are assumed not to reduce PSPS-related outage risk. Additional methodology details are documented in PG&E's Mitigation Effectiveness white paper.

3.2. Lifetime Cost Calculations

Overview: The WBCA calculates lifetime costs for each mitigation scenario using two primary cost components: initial capital costs and O&M costs. Initial capital costs reflect the one-time cost to install the mitigation alternative. O&M costs reflect the recurring costs to operate,

---

12 The PSPS Outage Risk output from the OPRM reflects an unadjusted reliability-risk value and does not incorporate PG&E's adopted enterprise risk attitude. Accordingly, WBCA applies a PSPS scaling factor derived from PG&E's Enterprise PSPS Bowtie analysis. The scaling factor is calculated as the Enterprise PSPS Bowtie Risk Score divided by the corresponding unadjusted risk value (natural-unit exposure multiplied by value-of-service assumptions). This derived scaling factor is then applied to the OPRM PSPS Outage Risk output to align PSPS risk values with PG&E's enterprise risk framework.

maintain, inspect, repair, or otherwise support the asset over its applicable life. For each mitigation alternative, the WBCA evaluates the present value of initial capital costs and incremental lifetime O&M costs relative to the baseline scenario. Incremental O&M costs are evaluated across multiple recurring cost categories, as described in Table 1 (Section 2.1.2), and are subsequently aggregated into the lifetime cost denominator used in the BCR calculation.

3.2.1. Initial Capital Spend

Capital Spend: Initial Capital Spend is calculated by applying planning-level installation capital cost assumptions to the primary overhead HFTD mileage addressed by each mitigation alternative. For undergrounding, these assumptions are applied on a per-mile basis to the HFTD portions of the circuit segment and adjusted for feasibility characteristics such as hard rock conditions, terrain gradient, and water crossings. The feasibility adjustment is informed by historical undergrounding project experience and is used to support Screen 2 benefit-cost evaluations. As projects advance through Screen 3 and subsequent stages of evaluation, additional scope, engineering, constructability, customer impact, and implementation information becomes available, and cost estimates are refined accordingly. The resulting installation capital cost is converted to a present-value revenue requirement using PG&E's applicable PVRR multiplier before being included in the lifetime cost component of the BCR calculation.

Formula
$$\boldsymbol{Lifetime\ Capital\ Spend}\ (\boldsymbol{Millions}\ \$) = (Primary\ Overhead\ HFTD\ Miles) * (Installation\ Capital\ Cost\ per\ Mile + Feasibility\ Multiplier * HF\ Feasibility\ Score) * PVRR$$

3.2.2. O&M Costs

O&M Costs reflect the recurring costs to operate, maintain, inspect, repair, and otherwise support the mitigation alternative over its applicable life. For WBCA purposes, O&M costs are evaluated as incremental lifetime costs relative to the baseline scenario and are converted to present value using the applicable real discount rate. Consistent with the cost categories summarized in Section 2.1.2, the model evaluates O&M costs using category-specific data sources, forecasting assumptions, and cost drivers. These categories include recurring maintenance and inspection activities, vegetation management associated with overhead facilities, outage-program costs associated with EPSS and PSPS operations, and forecast rebuild costs for distribution assets damaged by wildfires not caused by utility equipment or operations. Most O&M categories are modeled using cost-per-mile assumptions applied to the relevant overhead mileage, while EPSS and PSPS-related O&M costs are modeled on a cost-per-CMI basis because the underlying cost driver is customer interruption exposure rather than line mileage. For each category, O&M costs are estimated for the baseline and applicable mitigation alternatives, and the incremental difference relative to the baseline is included in the lifetime cost component of the BCR calculation.

Formula
$$\textbf{Present Value of O\&M Costs} = \sum_{t=1}^{\textbf{Asset Lifetime}} \frac{\textbf{Annual O\&M Costs}}{(1 + \textbf{Real Discount Rate})^t}$$

Annual O&M costs are converted to present value O&M costs by projecting the applicable annual cost stream over the expected asset life and discounting those future costs to present value using the real discount rate. This calculation is performed separately for both the baseline scenario and each mitigation alternative using the applicable cost assumptions. The net lifetime O&M cost attributable to a mitigation is then calculated as the difference between the mitigation lifetime O&M cost and the baseline lifetime O&M cost. This incremental lifetime O&M cost is included in the lifetime cost denominator used in the BCR calculation.

4. Output

The WBCA evaluates the lifetime costs and monetized risk-reduction benefits of each mitigation alternative at the circuit-segment level. For each evaluated mitigation, the model produces a BCR, which compares the present value of lifetime risk-reduction benefits to the present value of lifetime costs. The BCR provides a consistent framework for comparing mitigation alternatives across circuit segments and supports wildfire mitigation planning by identifying where specific mitigations provide the most significant risk reduction relative to cost.

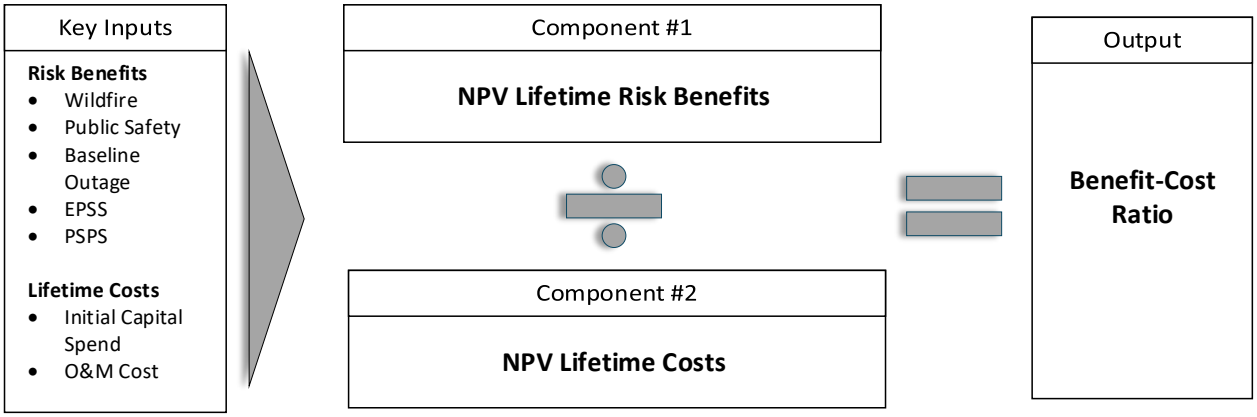

PG&E evaluates WBCA outputs alongside additional planning considerations that are outside the scope of the model, including factors such as ingress/egress considerations, residual tree-strike exposure, constructability constraints, and other program-specific requirements. As a result, WBCA serves as an important decision-support input, but is not the sole determinant of mitigation selection.

4.1. Benefit Cost Ratio Calculation (BCR)

Overview: The BCR provides a point-in-time estimate of the relative value of a mitigation alternative by comparing the present value of lifetime risk-reduction benefits to the present value of lifetime costs. The BCR is based on the model inputs, assumptions, and system conditions represented in the WBCA analysis and should be interpreted as a comparative planning metric rather than a prediction of future realized outcomes. A higher BCR indicates that a mitigation achieves greater risk reduction per dollar spent relative to alternatives with lower BCR values based on this point-estimate.

Figure 9 illustrates the overall BCR framework. The numerator consists of the net present value (NPV) of lifetime mitigated risk, including wildfire, public safety, Baseline Outage, EPSS, and PSPS benefits. The denominator consists of the NPV of all lifetime mitigation costs, including installation capital costs and incremental O&M costs relative to the baseline. The resulting ratio provides a standardized measure for comparing mitigation alternatives on a consistent basis across circuit segments.

Figure 9: Benefit Cost Ratio Calculation

Where:

Formula
$$\boldsymbol{BCR} = \frac{(NPV\ Lifetime\ Risk\ Benefit)}{(NPV\ Lifetime\ Costs)}$$ **Where:** • **NPV Lifetime Risk Benefit** = Present value of the sum of Wildfire, Public Safety, Baseline Outage, EPSS, and PSPS risk-reduction benefits over the applicable asset life. • **NPV Lifetime Costs** = Present value of installation capital costs and incremental lifetime O&M costs associated with the mitigation alternative.

Undergrounding Resource Model
Assumptions

Key Assumptions Used to Build the Resource Model	
Project Size	The resource model uses a miles-based approach to determine the required effort to deliver one mile of undergrounding (FTE/mile). Project size and difficulty have been consolidated and incorporated into the outputs from the productivity analysis and inform productivity rates.
Annual Mileage Target	The annual mileage targets are based on the overall program strategy as filed in the EUP. As planning scenarios are evaluated and implemented, the modeled mileage trajectory can be revised.
Construction Seasonality	Construction Seasonality was developed using the available construction schedule information and aggregates underground miles based on when construction starts and finishes in terms of months, regardless of the year of construction.
Schedule	The schedule assumptions are based on undergrounding project phase data (e.g. scoping, dependencies, construction etc., referred to as Workstream Progression data) developed by the Program to set non-construction target miles and is aligned with construction target miles.

*Projects will have the outputs from Formula 1 evaluated using a Collective or Separate Analysis. This is due to the method PG&E uses to estimate Overall Utility Risk, which subsumes the downstream impacts from a weather event and resulting customer outages in the risk calculation for each Circuit Segment. Because these downstream impacts are assumed within each Project's risk calculation, Collective and Ablation studies can be performed with a straightforward additive/subtraction approach, which effectively makes all risks strictly additive.

CORE CAPABILITY 3: SUPPORTING FORMULAS

Workpaper 010
Pacific Gas and Electric Company
Electrical Undergrounding Program
Core Capability 3: Supporting Formulas

Step 1 Estimate wildfire risk before EPSS/PSPS. WDRM supplies unitless risk points; unmitigated bowtie risk ($) is allocated to each circuit segment by its share of those points, enabling monetized consequence to be calculated.
Step 2 PROGRAMS ACTIVE: Apply the modeled wildfire reductions (80% risk reduction and 46.2% likelihood reduction), back-calculate consequence as risk ÷ likelihood, then add PSPS and EPSS outage risks to show the net risk trade-off.

		Wildfire											PSPS						EPSS						Outage Risk						Overall Utility Risk	
Portfolio Project #	Circuit Segment	Wildfire Likelihood - before EPSS/PSPS (AA)	Wildfire Likelihood - with EPSS/PSPS active (AS)	Combined Wildfire Likelihood - with EPSS/PSPS active (AC)	Unitless Wildfire Consequence (BB)	Implied Wildfire Consequence - before EPSS/PSPS (BBA)	Implied Wildfire Consequence - with EPSS/PSPS active (BS)	Combined Wildfire Consequence - with EPSS/PSPS active (BC)	WDRM wildfire risk points (K)	Wildfire Risk - before EPSS/PSPS (BWF)	Wildfire Risk - with EPSS/PSPS active (SWF)	Combined Wildfire Risk - with EPSS/PSPS active (XC)	PSPS Likelihood (O)	Combined PSPS Likelihood (P)	PSPS Consequence (Q)	Combined PSPS Consequence (R)	PSPS Risk (PR)	Combined PSPS Risk (T)	EPSS Likelihood (U)	Combined EPSS Likelihood (V)	EPSS Consequence (W)	Combined EPSS Consequence (X)	EPSS Rsk (ER)	Combined EPSS Risk (Z)	Outage Likelihood (AA)	Combined Outage Likelihood (AB)	Blended Outage Consequence (AC)	Combined Outage Consequence (AD)	Outage Risk (AE)	Combined Outage Risk (AF)	Overall Utility Risk (AG)	Combined Overall Utility Risk (AH)

CORE CAPABILITY 4: SUPPORTING FORMULAS

Workpaper 011
Pacific Gas and Electric Company
Electrical Undergrounding Program
Core Capability 4: Supporting Formulas
Directory

Sheet	Section of Core Capability 4 Section Addressed
4.1 - Risk Evaluation	The Large Electrical Corporation must detail its method for evaluating Ignition Risk and Outage Program Risk at future dates and the accumulation of Ignition Risk and Outage Program Risk over time. The Large Electrical Corporation must report instantaneous and cumulative risk and reliability scores at 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 25, 30, 35, 40, 45, 50, and 55 years into the future for all Confirmed Projects. Model Year 0 is defined to begin on the date the Large Electrical Corporation designates as the start date of the EUP (as set forth in the Target/Timeline Table), and subsequent times are measured at a fixed timeline from the same date.
4.2 - Project Timelines	The Large Electrical Corporation must describe how it uses estimated project timelines to model the reduction of risk and increase in reliability over time. For Undergrounding Projects, this timeline must include the estimated time for the project to acquire new rights-of-way, easements, permits, and CEQA review, if any. For non-undergrounding work, this timeline must use an estimate specific to the type of work using assumptions about the start time and construction time that are reasonable and consistent with the work being performed and assuming that the work will begin and be completed as soon as practicable. The Large Electrical Corporation must detail how these projections reflect its modeling of climate change as described in Core Capability 6.
4.3 - Discount Rates	If any discount rates are employed in the calculation of any KDMM, the Large Electrical Corporation must list them and explain their origin. If the discount rates change over time, the Large Electrical Corporation must explain how they change and why these changes are warranted. Changes must be in line with the CPUC Risk-based Decision-Making Framework Proceeding (Rulemaking 20-07-013 or its successor proceeding).

Core Capability 4: Supporting Formulas
4.1 - Risk Evaluation

Overview

Core Capability 4 of the EUP Guidelines requires that:

The Large Electrical Corporation must detail its method for evaluating Ignition Risk and Outage Program Risk at future dates and the accumulation of Ignition Risk and Outage Program Risk over time. The Large Electrical Corporation must report instantaneous and cumulative risk and reliability scores at 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 25, 30, 35, 40, 45, 50, and 55 years into the future for all Confirmed Projects. Model Year 0 is defined to begin on the date the Large Electrical Corporation designates as the start date of the EUP (as set forth in the Target/Timeline Table), and subsequent times are measured at a fixed timeline from the same date.

The supporting formulas at right detail the evaluations of instantaneous and cumulative values of future risks from Model Year 0 (Year 2028) for both Ignition Risk and Outage Program Risk; each of which follows a similar process of evaluation.

The evaluation begins by collecting Year 2028 / Model Year 0 valuations of the Pre-Mitigation and Residual (i.e., Post-Mitigation) Ignition Risk and Outage Program Risk of the Circuit Segment corresponding to the Confirmed Project and its mitigation activities. Depending on the Estimated Used and Useful Year, EY, of the Confirmed Project, the Instantaneous risk for each Model Year is evaluated by multiplying either the Year 2028 / Model Year 0 Pre-Mitigation or Residual Risk by the Climate Factor for each Model Year. Specifically, the Pre-Mitigation risk values are used in the years up to EY, and Residual risk values are used in years beyond EY. The Cumulative risk is then evaluated for each Model Year by summing the Instantaneous risk values from Model Year 0 through the current Model Year.

Estimated Project Completion / Segment Used and Useful Year

Est. Completion / Used and Useful Year	EY

2028 Ignition Risk for Circuit Segment

Note: Residual Risks by Mitigation (IRP1 through IRP4) are not reported with Instantaneous and Cumulative Risk metrics.

Pre-Mitigation Risk (IRA0), A : 'ante'	IRA0
Residual Risk (IRP0), P : 'post'	IRP0 = IRP1 + IRP2 + IRP3 + IRP4
Residual Risk, Mitigation 1 (IRP1)	IRP1
Residual Risk, Mitigation 2 (IRP2)	IRP2
Residual Risk, Mitigation 3 (IRP3)	IRP3
Residual Risk, No Mitigation (IRP4)	IRP4

2028 Outage Program Risk for Circuit Segment

Note: Residual Risks by Mitigation (ORP1 through ORP4) are not reported with Instantaneous and Cumulative Risk metrics.

Pre-Mitigation Risk (ORA0), A : 'ante'	ORA0 = ERA0 + PRA0
Residual Risk (ORP0), P : 'post'	ORP0 = ERP0 + PRP0
Residual Risk, Mitigation 1 (ORP1)	ORP1 = ERP1 + PRP1
Residual Risk, Mitigation 2 (ORP2)	ORP2 = ERP2 + PRP2
Residual Risk, Mitigation 3 (ORP3)	ORP3 = ERP3 + PRP3
Residual Risk, No Mitigation (ORP4)	ORP4 = ERP4 + PRP4

2028 EPSS Risk for Circuit Segment

Note: Residual Risks by Mitigation (ERP1 through ERP4) are not reported with Instantaneous and Cumulative Risk metrics.

Pre-Mitigation Risk (ERA0), A : 'ante'	ERA0
Residual Risk (ERP0), P : 'post'	ERP0 = ERP1 + ERP2 + ERP3 + ERP4
Residual Risk, Mitigation 1 (ERP1)	ERP1
Residual Risk, Mitigation 2 (ERP2)	ERP2
Residual Risk, Mitigation 3 (ERP3)	ERP3
Residual Risk, No Mitigation (ERP4)	ERP4

2028 PSPS Risk for Circuit Segment

Note: Residual Risks by Mitigation (PRP1 through PRP4) are not reported with Instantaneous and Cumulative Risk metrics.

Pre-Mitigation Risk (PRA0), A : 'ante'	PRA0
Residual Risk (PRP0), P : 'post'	PRP0 = PRP1 + PRP2 + PRP3 + PRP4
Residual Risk, Mitigation 1 (PRP1)	PRP1
Residual Risk, Mitigation 2 (PRP2)	PRP2
Residual Risk, Mitigation 3 (PRP3)	PRP3
Residual Risk, No Mitigation (PRP4)	PRP4

Instantaneous and Cumulative Ignition Risk and Outage Program Risk by Model Year

Year (YRx)	Model Year (MYx)	Climate Factor Dividend (CDx)	2028-Normalized Climate Factor (Cx = CDx / CD0)	Instantaneous Ignition Risk Multiplicand (IRMx = if (YRx < EY) then (IRAx) else (IRPx))	Instantaneous Ignition Risk (IRIx = IRMx * Cx)	Cumulative Ignition Risk (IRCx = ∑IRIx; x: {0, …, MYx})	Instantaneous EPSS Risk Multiplicand (ERMx = if (YRx < EY) then (ERAx) else (ERPx))	Instantaneous EPSS Risk (ERIx = ERMx * Cx)	Cumulative EPSS Risk (ERUx = ∑ERIx; x: {0, …, MYx})	Instantaneous PSPS Risk Multiplicand (PRMx = if (YRx < EY) then (PRAx) else (PRPx))	Instantaneous PSPS Risk (PRIx = PRMx * Cx)	Cumulative PSPS Risk (PRUx = ∑PRIx; x: {0, …, MYx})	Instantaneous Outage Program Risk Multiplicand (ORMx = if (YRx < EY) then (ORAx) else (ORPx))	Instantaneous Outage Program Risk (ORIx = ORMx * Cx)	Cumulative Outage Program Risk (ORCx = ∑ORIx; x: {0, …, MYx})

Instantaneous and Cumulative Ignition Risk and Outage Program Risk by Model Year Numerical Examples - Low Risk Scenario

Low Risk Scenario

Estimated Project Completion / Segment Used and Useful Year

Est. Completion / Used and Useful Year	2030

2028 Ignition Risk for Circuit Segment

Pre-Mitigation Risk (IRA0), A : 'ante'	$1.00
Residual Risk (IRP0), P : 'post'	$0.13

2028 Outage Program Risk for Circuit Segment

Pre-Mitigation Risk (ORA0), A : 'ante'	$0.09
Residual Risk (ORP0), P : 'post'	$0.02

2028 EPSS Risk for Circuit Segment

Pre-Mitigation Risk (ERA0), A : 'ante'	$0.02
Residual Risk (ERP0), P : 'post'	$0.02

2028 PSPS Risk for Circuit Segment

Pre-Mitigation Risk (PRA0), A : 'ante'	$0.07
Residual Risk (PRP0), P : 'post'	$0.00

Instantaneous and Cumulative Ignition Risk and Outage Program Risk by Model Year Numerical Examples - Medium Risk Scenario

Medium Risk Scenario

Estimated Project Completion / Segment Used and Useful Year

Est. Completion / Used and Useful Year	2029

2028 Ignition Risk for Circuit Segment

Pre-Mitigation Risk (IRA0), A : 'ante'	$2.00
Residual Risk (IRP0), P : 'post'	$0.25

2028 Outage Program Risk for Circuit Segment

Pre-Mitigation Risk (ORA0), A : 'ante'	$6.60
Residual Risk (ORP0), P : 'post'	$3.78

2028 EPSS Risk for Circuit Segment

Pre-Mitigation Risk (ERA0), A : 'ante'	$3.78
Residual Risk (ERP0), P : 'post'	$3.78

2028 PSPS Risk for Circuit Segment

Pre-Mitigation Risk (PRA0), A : 'ante'	$2.82
Residual Risk (PRP0), P : 'post'	$0.00

Instantaneous and Cumulative Ignition Risk and Outage Program Risk by Model Year Numerical Examples - High Risk Scenario

High Risk Scenario

Estimated Project Completion / Segment Used and Useful Year

Est. Completion / Used and Useful Year	2028

2028 Ignition Risk for Circuit Segment

Pre-Mitigation Risk (IRA0), A : 'ante'	$4.00
Residual Risk (IRP0), P : 'post'	$0.50

2028 Outage Program Risk for Circuit Segment

Pre-Mitigation Risk (ORA0), A : 'ante'	$22.59
Residual Risk (ORP0), P : 'post'	$16.08

2028 EPSS Risk for Circuit Segment

Pre-Mitigation Risk (ERA0), A : 'ante'	$16.08
Residual Risk (ERP0), P : 'post'	$16.08

2028 PSPS Risk for Circuit Segment

Pre-Mitigation Risk (PRA0), A : 'ante'	$6.51
Residual Risk (PRP0), P : 'post'	$0.00

[1] Used and Useful Date refers to the date the last sub-project will be energized on a given Circuit Segment. Used and Useful Dates are estimates only and can vary as Projects are scoped, planned and constructed.

Electrical Undergrounding Plan (EUP) Discount Rate Scenario Details

1. Weighted Average Cost of Capital (WACC)				Notes
Nominal Pre-Tax CPUC Weighted Average Cost of Capital (WACC)				(1)
	Cost	**Weight**	**Weighted Cost**	
Return on Common Equity	10.28%	52.00%	5.35%	
Return on Preferred Equity	5.52%	0.50%	0.03%	
Return on Long-Term Debt	4.80%	47.50%	2.28%	
Nominal Pre-Tax WACC			**7.65%**	
Income Tax Rates				
Federal Income Tax Rate			21.00%	(2)
State Income Tax Rate			8.84%	(3)
Combined Income Tax Rate			**27.98%**	(4)
Nominal After-Tax CPUC WACC				
	Cost	**Weight**	**Weighted Cost**	
Return on Common Equity	10.28%	52.00%	5.35%	
Return on Preferred Equity	5.52%	0.50%	0.03%	
Return on Long-Term Debt	3.46%	47.50%	1.64%	
Nominal After-Tax WACC (ATWACC)			**7.02%**	
Round to the nearest			0.50%	(5)
Rounded Nominal ATWACC			**7.00%**	
2. Societal Discount Rate				
Social Rate of Time Preference (SRTP)			**2.00%**	(6)
3. Hybrid Discount Rate (for safety and reliability terms)				
Effective Average Inflation Rate				(7)
2014 Annual Average CPI			246.055	
2024 Annual Average CPI			341.951	
10-year Effective Average Inflation Rate			**3.35%**	
Effective Average Per-Capita Real Growth Rate of Wages				(8) (9) (10) (11)
2014 Mean Annual Wage			$54,920	
2024 Mean Annual Wage			$81,804	
10-year Effective Average Per-Capita Real Growth Rate of Wages			**0.7%**	
Hybrid Discount Rate for Safety and Reliability terms in BCR			**6.1%**	(12) (13)

Notes:

(1) Cost of Capital from CPUC D.24-10-008. https://docs.cpuc.ca.gov/PublishedDocs/Published/G000/M544/K150/544150643.PDF

(2) Federal Income Tax data is taken from IRS Publication 542, Corporations: https://www.irs.gov/pub/irs-pdf/p542.pdf

(3) State Income Tax data is taken from California Franchise Tax Board, Business tax rates: https://www.ftb.ca.gov/file/business/tax-rates.html

(4) Assume State Taxes are deductible from Federal Taxable Income

(5) PG&E's 2024 RAMP Application, PG&E-2, pg. 2-40: https://www.cpuc.ca.gov/-/media/cpuc-website/divisions/safety-policy-division/reports/2024-ramp-application-pge051524.pdf

(6) Methodology from the CPUC on how to apply SRTP is discussed in the Public Advocates Office, Informal Comments on Questions for Stakeholders Regarding the CPUC SB-884 Guidelines (Nov. 12, 2024), section II.D, available at: https://www.cpuc.ca.gov/-/media/cpuc-website/divisions/safety-policy-division/meeting-documents/informal-responses-to-postworkshop-questions.pdf.
- Social Rate of Time Preference (SRTP) values from U.S. Office of Management and Budget (OMB) Circular A-4: https://www.reginfo.gov/public/jsp/EO/fedRegReview/CircularA4Appendix.pdf
- Social Rate of Time Preference (SRTP) values can also be found at the Direct White House website: https://www.whitehouse.gov/wp-content/uploads/2023/11/CircularA-4DiscountHistory.pdf

(7) Annual Average CPI is from: https://dir.ca.gov/oprl/CPI/CPICalculator/CpiCalculator.aspx
Please note: at the time the WBCA was initially developed the latest year with annual average CPI was 2024 (As of 8/7/25)

(8) Employment and Wage Statistics data encompassing 2016-2025: https://labormarketinfo.edd.ca.gov/data/oes-employment-and-wages.html#DashB: https://labormarketinfo.edd.ca.gov/data/oes-employment-and-wages.html#DashB

(9) Employment and Wage Statistics data encompassing 2006-2015 data: https://labormarketinfo.edd.ca.gov/data/OES_Employment_and_Wages_2006-2015.html

(10) Employment and Wage Statistics data uses 1st Quarter State of California Excel file for 2024 wage data and 2015 1st Quarter State of California Excel file for 2014 wage data (to align to CPI years)

(11) Employment and Wage Statistics data uses estimates encompassing all occupations in the two attachments noted in footnotes 8 and 9. This is represented as code "00-0000" in the "SOC Code" column and "Total all occupations" in the "Occupation Field" column. The resulting value is taken from the 'Mean Annual Wage' column

(12) The methodology for calculating the hybrid discount rate is detailed in California Public Utilities Commission (CPUC). Decision 24-05-064: Phase 3 Decision, Rulemaking 20-07-013, May 30, 2024, pgs. 103-104 which is available here: https://docs.cpuc.ca.gov/PublishedDocs/Published/G000/M533/K099/533099839.PDF)

(13) For Hybrid Discount Rate Scenarios, the Hybrid discount rate is applied to Safety and Reliability components in numerator, while WACC is applied to Financial components of numerator and denominator as detailed in *California Public Utilities Commission (CPUC). Decision 24-05-064: Phase 3 Decision, Rulemaking 20-07-013, May 30, 2024, p. 103 which is available here:* https://docs.cpuc.ca.gov/PublishedDocs/Published/G000/M533/K099/533099839.PDF)

PACIFIC GAS AND ELECTRIC COMPANY

ELECTRICAL UNDERGROUNDING PLAN

ATTACHMENT B

WP013

CORE CAPABILITY 6: SUPPORTING FORMULAS

Workpaper 013
Pacific Gas and Electric Company
Electrical Undergrounding Program
Core Capability 6: Supporting Formulas
Directory

Sheet	Section of Core Capability 4 Section Addressed
6.3 - Baseline Risk	To establish an initial Baseline, the Large Electrical Corporation must model the risk landscape assuming that no EUP Undergrounding Projects are constructed. This Baseline modeling must include any non-EUP wildfire mitigation activity in Tier 2 or 3 HFTDs. In subsequent Baselines, the Large Electrical Corporation must include activity outside of the EUP program that the Large Electrical Corporation has initiated or completed since the establishment of the previous Baseline.
6.5 - Project Timelines	To establish an initial Baseline, the Large Electrical Corporation must model the risk landscape assuming that no EUP Undergrounding Projects are constructed. This Baseline modeling must include any non-EUP wildfire mitigation activity in Tier 2 or 3 HFTDs. In subsequent Baselines, the Large Electrical Corporation must include activity outside of the EUP program that the Large Electrical Corporation has initiated or completed since the establishment of the previous Baseline. This modeling will attempt to account for climate change. Baselines must be measured and reported at the same cadence as other risk model landscape components at 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 25, 30, 35, 40, 45, 50, and 55 years. Each Baseline must indicate the version of the modeling system and the model calibration(s) that were used to evaluate it. The Baselines must also indicate the date the Baseline was created, and the naming scheme of the Baselines must be consistent across the lifetime of the EUP. Any comparison of an Undergrounding Project or Alternative Mitigation to a Baseline must indicate what Baseline the comparison is being made to. For Project-Level comparisons, such as the evaluation of the Project-Level Standard, the Baseline also establishes the pre-mitigation Circuit Segment length and alignment on which to make the future comparisons.

Workpaper 013
Pacific Gas and Electric Company
Electrical Undergrounding Program
Core Capability 6: Supporting Formulas
Core Capability 6.3

Core Capability 6.3: Develop a system to record Baselines and historical model calibrations. A new Baseline must be recorded at least once per calendar year. This new Baseline must account for all physical changes to the electrical distribution infrastructure performed during that year, through the EUP or any other mechanism

**The baselining of risk occurs annually and follows the same process from year-to-year, where the new baseline Circuit Segment Risk of Year N is the residual risk of the prior year.*

Workpaper 013
Pacific Gas and Electric Company
Electrical Undergrounding Program
Core Capability 6: Supporting Formulas
Core Capability 6.5

Overview

Core Capability 6 of the EUP Guidelines requires that:

...[T]he Large Electrical Corporation must develop a system to record Baselines and historical model calibrations. A new Baseline must be recorded by the Large Electrical Corporation at least once per calendar year. This new Baseline must account for all physical changes to the electrical distribution infrastructure performed during that year, through the EUP or any other mechanism.

To establish an initial Baseline, the Large Electrical Corporation must model the risk landscape assuming that no EUP Undergrounding Projects are constructed. This Baseline modeling must include any non-EUP wildfire mitigation activity in Tier 2 or 3 HFTDs. In subsequent Baselines, the Large Electrical Corporation must include activity outside of the EUP program that the Large Electrical Corporation has initiated or completed since the establishment of the previous Baseline.

This modeling will attempt to account for climate change. Baselines must be measured and reported at the same cadence as other risk model landscape components at 0, 1, 2, 3, 4, 5, 6,7, 8, 9, 10, 15, 20, 25, 30, 35, 40, 45, 50, and 55 years.

The supporting formulas at right detail the evaluations of instantaneous and cumulative values of Baseline risks from Model Year 0 (Year 2028) for both Ignition Risk and Outage Program Risk; each of which follows a similar process of evaluation.

Additionally, it is noteworthy that the formulations for evaluating the Baseline risks for Core Capability 6 are similar to those of the future risks for Core Capability 4. The salient difference is that the Baseline risk evaluations consider only the effects of mitigation activities completed since Year 2028, and thus rely on knowing an Actual Energization Year for the Circuit Segment, as applicable. In contrast, the future risk evaluations for Core Capability 4 consider the effects of mitigation activities yet to occur, and thus rely on knowing a future Estimated Energization Year, as applicable. Despite these contextual differences, the primary process of evaluation remains the same.

The evaluation begins by collecting Year 2028 / Model Year 0 valuations of the Pre-Mitigation and Residual (i.e., Post-Mitigation) Ignition Risk and Outage Program Risk of the Circuit Segment corresponding to its mitigation activities, if any have been performed since Year 2028. Depending on the Actual Energization Year, EY, of the Circuit Segment following implementation of mitigation activities, the Instantaneous risk for each Model Year is evaluated by multiplying either the Year 2028 / Model Year 0 Pre-Mitigation or Residual Risk by the Climate Factor for each Model Year. Specifically, the Pre-Mitigation risk values are used in the years up to and including EY, and Residual risk values are used in years beyond EY. The Cumulative risk is then evaluated for each Model Year by summing the Instantaneous risk values from Model Year 0 through the current Model Year.

Actual Project Completion / Segment Energization Year

Act. Completion / Energization Year	EY

2028 Ignition Risk for Circuit Segment

Pre-Mitigation Risk (IRA0), A : 'ante'	IRA0
Residual Risk (IRP0), P : 'post'	IRP0 = IRP1 + IRP2 + IRP3 + IRP4
Residual Risk, Mitigation 1 (IRP1)	IRP1
Residual Risk, Mitigation 2 (IRP2)	IRP2
Residual Risk, Mitigation 3 (IRP3)	IRP3
Residual Risk, No Mitigation (IRP4)	IRP4

2028 Outage Program Risk for Circuit Segment

Pre-Mitigation Risk (ORA0), A : 'ante'	ORA0 = ERA0 + PRA0
Residual Risk (ORP0), P : 'post'	ORP0 = ORP1 + ORP2 + ORP3 + ORP4
Residual Risk, Mitigation 1 (ORP1)	ORP1 = ERP1 + PRP1
Residual Risk, Mitigation 2 (ORP2)	ORP2 = ERP2 + PRP2
Residual Risk, Mitigation 3 (ORP3)	ORP3 = ERP3 + PRP3
Residual Risk, No Mitigation (ORP4)	ORP4 = ERP4 + PRP4

2028 EPSS Risk for Circuit Segment

Pre-Mitigation Risk (ERA0), A : 'ante'	ERA0
Residual Risk (ERP0), P : 'post'	ERP0 = ERP1 + ERP2 + ERP3 + ERP4
Residual Risk, Mitigation 1 (ERP1)	ERP1
Residual Risk, Mitigation 2 (ERP2)	ERP2
Residual Risk, Mitigation 3 (ERP3)	ERP3
Residual Risk, No Mitigation (ERP4)	ERP4

2028 PSPS Risk for Circuit Segment

Pre-Mitigation Risk (PRA0), A : 'ante'	PRA0
Residual Risk (PRP0), P : 'post'	PRP0 = PRP1 + PRP2 + PRP3 + PRP4
Residual Risk, Mitigation 1 (PRP1)	PRP1
Residual Risk, Mitigation 2 (PRP2)	PRP2
Residual Risk, Mitigation 3 (PRP3)	PRP3
Residual Risk, No Mitigation (PRP4)	PRP4

Executive Summary

The Distribution Event Probability Models (DEPM) are used by PG&E to quantify and categorized failure and ignition events from the overhead distribution network assets. The event probability model suite predicts the relative likelihood of failure and ignition events for distribution assets for a wildfire season.

The DEPM model suite is comprised of a top-level Probability of Ignition model and a supporting suite of Probability of Failure/Outage models. There are two types of Probability of Event Failure/Outage models, Equipment and Contact From Object. Equipment models address failures of physical equipment assets on the distribution grid. Contact From Object models predict failures that result when an external object such as a tree, vehicle, or animal contact a grid asset.

The DEPM supports the Wildfire Distribution Risk Model (WDRM) mission to quantify and categorize wildfire risk from overhead distribution network assets. The relative wildfire risk results produced by the WDRM inform the PG&E Wildfire Mitigation Plan (WMP) as well as specific mitigation program work plans to help realize the company stand, *"Catastrophic wildfires will stop"*.

This document describes DEPM version 4 (v4) development by the PG&E Risk and Data Analytics (RaDA) team and highlights improvement implemented over its predecessor, DEPM v3.

DEPM v4 Improvements

DEPM v4 features several significant improvements to the modeling of asset failure and ignition events:

- Substantial improvements to data quality of asset records, event locations, and event causes resulted in improved model performance.
- Model development training data sets were adjusted for the impact of EPSS.
- Several equipment asset models were upgraded from spatial to asset time-series models, resulting in improved model performance and direct aggregation of risk by asset to circuit segments, which in turn improved relative circuit segment risk values for WDRM v4.
- Several new features were added to the Vegetation models to better account for climate change effects and to improve model performance.
- Introduction of event cause and equipment type interaction terms to the Probability of Ignition given Outage model to improve performance for causal pathways that share underlying characteristics for weather and fuels.

DEPM v4 Event Probability Insights

The improvements implemented for DEPM v4 have resulted in generally improved performance metrics when compared with the v3 model. The newly developed equipment asset models provide more causal insight into outage and ignition events for mitigation planning.

An analysis of the v3 and v4 probability of ignition values revealed that the v4 results provide more relative sensitivity for comparing assets, locations, and circuit segment aggregated values. One contributor to the increased risk sensitivity is that the probability of ignition range for v4 has increased by more than an order of magnitude over the range produced by the v3 model. The increased range resulted from the introduction of the new equipment asset models and improved model data quality. Consequently, the probability of ignition for v4 has a larger influence on circuit segment wildfire risk values and ranks for WDRM v4 than for WDRM v3.

DEPM v4 Event Future Plans

PG&E has historically released new versions of the WDRM, and the supporting DEPM, on an annual cycle. In the future, WDRM releases are to be aligned with the Wildfire Mitigation Plan (WMP) filing schedule rather than annually. WDRM v4 is intended to support PG&E's 2026 WMP.

DEPM v4 delivered several features planned for 2024 and 2025 development. Future event probability models will aim to improve on existing features and capabilities while addressing additional unquantified risk. Some of the expected future development includes:

- Extending the event probability model time horizon beyond the wildfire season to cover the entire calendar year in support of public safety and reliability risk models.
- Development of new Underground Equipment Asset models.
- Additional models will be transitioned from using a spatial modeling to a temporal modeling algorithm to improve performance by accounting for changes in model features over time.
- Continuous improvement efforts to the capture, detail, maintenance, and curation of data sets used for the event probability models.
- Incorporate improved FPI model predictions from Meteorology into the Probability of Ignition model.

1 Introduction

1.1 Event Probability Model Overview

A key component in evaluating the operational risk resulting from PG&E's electrical distribution network is the capability to predict the types and frequency of failure, outage, and ignition events. The Distribution Network Event Probability Models integrate collective knowledge about historical distribution grid events to estimate the likelihood of future events.

The Event Probability Model predictions can be used to support multiple types of risk assessment for planning operations and maintenance activities. The most significant use of the models, currently, is contributing to the determination of Wildfire risk to inform long-term mitigation work planning. The model predictions can also be used to assess other types of risk such as Public Safety and Reliability.

1.2 Event Probability Model Types

The types of probability models produced for predicting future events are:

- Probability of Outage models
  - Equipment Asset models
  - Contact From Object models
- Probability of Ignition (Given Outage) model

1.2.1 Equipment Asset Model Types

Equipment Asset models consider event history and contributing factors to predict failure of specific types of electrical equipment. Each asset model uses a unique set of inputs (covariates) from a pool of asset attributes and environmental conditions. For some assets, unique models (sub-sets), are produced for specific types of failures.

The following Equipment Asset models were produced for v4:

- Capacitor Bank
- Dynamic Protection Device (DPD)
- Fuse
- Primary Conductor
  - Line Slap
  - Wire Down
  - Other
- Secondary Conductor
- Support Structure
  - Electrical Failure
  - Structural Failure
- Switch
- Transformer
  - Leaking
  - Failure
- Voltage Regulator
- Other Equipment

1.2.2 Contact From Object Model Types

Contact From Object models consider event history and contributing factors to predict failure caused by contact from foreign objects with electrical assets. Each contact model uses a unique set of inputs (covariates) from a pool of object attributes and environmental conditions. All contact models provide unique models (sub-sets) for specific types of contact failures.

The following Contact From Object models were developed for v4:

- Animal
  - Bird
  - Squirrel
  - Other
- Third-Party
  - Balloon
  - Vehicle
  - Other
- Vegetation
  - Branch
  - Trunk
  - Other

1.2.3 Probability of Ignition Model

The probability of ignition is the likelihood that an asset-based ignition will occur during a fire season. Probability of Ignition is predicted by the Probability of Ignition Given Outage model using the probability of outage predictions from all of the Asset Equipment and Contact From Object models along with other attributes such as environmental conditions. Fire season probabilities of ignitions are individually predicted for each specific Asset Equipment and Contact From Object Model.

1.3 Wildfire Distribution Risk Model (WDRM)

The WDRM is the primary risk model that PG&E uses to prioritize mitigation work to reduce wildfires initiated by the distribution grid. Mitigation program work planners use the WDRM results, along with their mitigation program work planning tools to develop work plans that systematically reduce wildfire risk while considering constraints such as budget allocation, human and equipment resource capacity, and regulatory commitments.

The WDRM is released periodically by the RaDA team to quantify the risk related to PG&E's overhead distribution equipment assets, which consist of overhead transformers, poles and other parts of support structures, lines (conductors), and line-related equipment such as interrupters. The WDRM provides predictions of wildfire risk that occurs during an annual wildfire season of June 1st through November 30th.

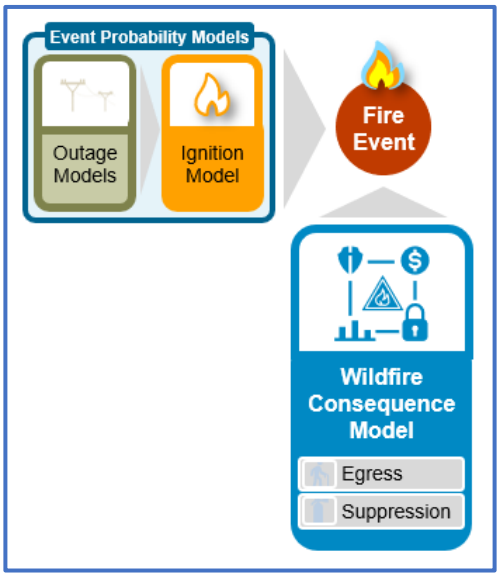

Figure 1 - Wildfire Risk Model

Wildfire risk is calculated from two component values, Probability of Ignition and Wildfire Consequence. Probability of Ignition, p(i), is the annual fire season likelihood that an ignition will originate at the location of an electrical asset. p(i) is predicted by the Event Probability Models described in this document. Wildfire Consequence, WFC, is the expected outcome, or consequence of a fire that ignites at a specific geographic location (of an asset). The Wildfire Consequence Model provides ignition event consequence values and is described in a separate document.

The wildfire risk calculation is:

$$Risk_{loc} = p(i)_{loc} * WFC_{loc} = LoRE_{loc} * CoRE_{loc}$$

where:

CoRE	Consequence of Risk Event, an alternative name for WFC
loc	Asset location expressed as a 100m square pixel within the PG&E service territory
LoRE	Likelihood of Risk Event, an alternative name for p(i)
p(i)	Probability of Ignition
Risk	Wildfire risk
WFC	Wildfire consequence

1.4 Document Content

This document is part of the documentation suite for the Wildfire Distribution Risk Model (WDRM) v4:

- WDRM v4 Documentation
- Wildfire Fire Consequence Model v4 Documentation
- Distribution Network Event Probability Models v4 Documentation (this document)
- RaDA Algorithms and Methodologies

The intent of this document is to present the development, performance, and use of the Distribution Event Probability Models that support the wildfire risk predictions provided by WDRM v4. Source data, modeling approach, and resulting probability predictions are described in detail.

This document seeks to provide the lay reader with a broad understanding of the event probability models. It is not intended to provide comprehensive detailed mathematical or scientific descriptions of all methods used to produce the Event Probability Models.

2 Event Probability Model Improvements

2.1 Version Evolution

The event probability models have been expanded in scope with each release. Generally, with each release new causal models have been introduced that improve the ability of work planners to select the correct mitigation strategy to minimize the outages and failures that can result in ignitions along the distribution grid. Figure 2 provides an overview of how the event probability models have evolved with each version release.

Figure 2 – Event Probability Model Evolution

2.2 Probability of Failure/Outage Improvements

Several general improvements focused on data pipelines and quality were made to the v4 event probability failure and outage models, including:

- Addition of 2022 events for Failure/Outage and Ignitions.
- Association of historical equipment failure events with the equipment ID of the asset that failed, even if that asset was removed from service. This included a review of the wildfire season events for each time series asset model.
- Enhanced data set reliability through implementation of data pipeline best practices including unit test coverage and setting schema and value data quality expectations.
- Review of the keyword text extraction to identify failure sub drivers based on repair records and field notes. This is particularly important for outage events, where the primary cause and sub cause may not be updated after an initial troubleshooter review.
- Enhanced latitude and longitude locations from vegetation outage inspections for improved fault location of vegetation failure events.

Most asset models have been upgraded to produce asset-based time-series model results rather than spatial grid pixel predictions, enabling the direct aggregation of asset event probabilities and risks to its specific circuit segment for v4. In contrast, v3 asset results were assign to its containing 100m by 100m grid pixel and the asset event probabilities and risk were shared equally with all circuit segments that touched the pixel. This upgrade results in better understanding of relative circuit segment risk for the WDRM. The following models produce asset-specific time-series results for v4:

- Capacitor Bank
- DPD
- Fuse
- Primary Conductor
- Support Structure
- Switch
- Transformer
- Voltage Regulator

Several new features were added to the Vegetation models, accounting for climate change and improving model performance:

- Standardized Precipitation and Evapo-Transpiration Index (SPEI)
- Climatic Water Deficit (CWD)
- California High Hazard Zones from CalFIRE
- Tree Canopy Density from Planet Labs
- Wind Strike Potential
- Improved tree failure location data

2.3 Probability of Ignition Improvements

The key improvements for the Probability of Ignition model include:

- Introduction of event cause and equipment type interaction terms to the Probability of Ignition given Outage model to improve performance for causal pathways that share underlying characteristics for weather and fuels.
- Removing the impact of EPSS activation from the ignitions event training data set.
- Incorporating the expanded set of Probability of Failure/Outage causal models.

3 Event Probability Model Descriptions

3.1 Overview

The following sections describe the development and results for the complete set of v4 probability models. The primary purpose of these models, when combined, is to produce a set of electrical assets probability of ignition estimates for a future fire season for the WDRM.

The event probability models are comprised of a top-level Probability of Ignition model and a supporting suite of Probability of Failure/Outage models. There are two types of Probability of Event Failure/Outage models, Equipment and Contact From Object. Equipment models address failures of physical equipment assets on the distribution grid. Contact From Object models predict failures that result when an external object such as a tree, vehicle, or animal contact a grid asset.

As noted above, the primary purpose driving development of the Event Probability Models is to support the WDRM. However, the Probability of Failure Models can support other risk evaluation needs, such as Reliability and Public Safety Risks.

The v4 event probability models provide event likelihood predictions for distribution network assets as recorded in PG&E's Electric Distribution Geographic Information System (EDGIS) as of January 1st, 2023.

3.2 Model Development Process

All event probability models are developed following an iterative process. A high-level view of the development process is shown in *Figure 3*.

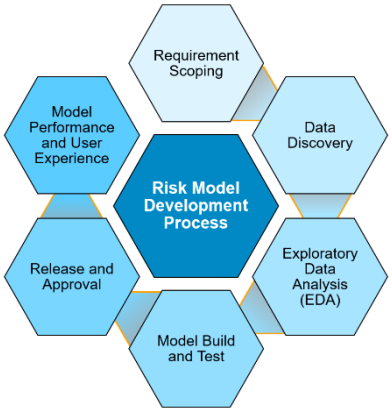

Figure 3 - Model Development Process

Requirement Scoping – Encompasses user feedback, new user requirements, potential performance improvements, and new or desired causal information to set model development goals.

Data Discovery – Researching new data sources, obtaining updates to refresh existing data sources, and cleaning and validating data for potential model use.

Exploratory Data Analysis (EDA) – Data analysis and investigation to determine fitness for modeling.

Model Build and Test – Successive builds of proposed models verified for performance against independent testing data.

Release and Approval – Candidate release models are published to the user community for critique. Viable release candidates are presented through a governance process to gain approval for general release in support of wildfire mitigation work planning.

Model Performance and User Experience – The approved model is monitored for performance against actual events and user feedback is collected to inform the next iteration of model development.

This is a very simplified description of the risk modeling process. Model development is an iterative learning process. As knowledge is gained, model development may require a return to a prior process step.

3.2.1 Model Performance and Feature Metrics

Several metrics are used during the model development process to gauge model quality. Model performance metrics are used to gain insight into how a model performs on data its algorithm hasn't been exposed to during model development. Model feature metrics provide insight into how helpful and influential model feature inputs are to the model outcomes.

Model performance metrics are typically generated by withholding an out-of-sample test data set from the data gathered for model training. After fitting a candidate model using a machine learning algorithm, the candidate is exercised to generate model predictions for the test data set. The candidate model predictions are compared against the actual test data set outcomes to produce performance metrics. The performance metrics commonly used by the RaDA team metrics used for evaluating machine learning models are:

- ROC AUC Curves
- Precision-Recall Curves and Average Precision
- Top 20% Concentration Factor

Features metrics are used to help explain how a machine learning model is influenced by its covariates, why the model predicts a particular set of results, and guides subsequent feature selection for candidate models. Feature metrics are often reviewed with Subject Matter Experts (SMEs) to understand whether or not expected covariates are important to the model and, if not, why not. Conversely, feature metric reviews also carefully consider the importance of unexpected covariates. The most common feature metrics used by the RaDA team include:

- Feature Importance Plots
- SHAP Plots

The model performance and feature metrics are explained in more detail in the RaDA Algorithms and Methodologies document.

3.3 EPSS Impact on Event Modeling

The introduction of Enhanced Powerline Safety Settings (EPSS) as an operational tool for preventing wildfires impacts the target, or training, data sets used to build and calibrate the event probability models. EPSS activation, in general, increases the number of outages for protected conductors while decreasing the number of ignitions. However, as EPSS is not always enabled, the event probability models need to predict event likelihood in the absence of any optional operational control measures. Therefore, the impact of EPSS is removed from target failure and ignition seasonal counts prior to event model calibration.

The EPSS causal impact is inferred from the 2021 EPSS trial period, which was conducted during the 2021 fire season from July 28th through October 23rd, 2021. The trial was conducted on 160 circuits whose protective devices were initially set to the most sensitive default trip setting and were transitioned to less sensitive engineer-specified EPSS settings during the trial. By the start of the 2022 fire season, EPSS settings were available on virtually all circuits in the High Fire Threat District (HFTD), with the settings activated only during periods of elevated ignition risk as determined using PG&E Meteorology's FPI R-score and wind condition forecasts.

The EPSS implementation team estimated program impacts by comparing event rates for EPSS protected circuits from the four years, 2017 – 2020, prior to EPSS enablement and under conditions that would have resulted in

EPSS activation with event rates from when the settings were enabled during the 2022 fire season. Synthetic Difference in Differences (SDID) estimation was applied to event rates for EPSS protected circuits during time periods when EPSS was not enabled in comparison with event rates for non-EPSS protected circuits across the entire wildfire season. The SDID analysis produced estimates of how much EPSS activation increases the rate of outage events and decreases the rate of ignition events.

2022 wildfire season EPSS daily activation records were used to correct the observed event frequency for distribution grid pixel locations where EPSS would likely be activated for future fire seasons. For example, take a set of grid pixels with EPSS protection where:

Variable	Value	Description
$p(e)_{Observed}$	10	Count of observed events, outage or ignition, in a fire season
f_{EPSS}	0.15	Fraction of fire season days with EPSS activated
α_{EPSS}	0.1	Fractional change in events with EPSS activated from SDIS analysis
$p(e)_{Corrected}$	---	Fire season event count corrected for EPSS impact

The EPSS event count correction factor is determined from the observed count, the fraction of EPSS activation days in the fire season, and the fractional change in events with EPSS activated:

$$p(e)_{Observed} = p(e)_{Corrected} * (1 - f_{EPSS}) + p(e)_{Corrected} * (1 + \propto_{EPSS}) * f_{EPSS}$$

Substituting in the example values:

$$10 = p(e)_{Corrected} * (1 - 0.15) + p(e)_{Corrected} * (1 + 0.1) * 0.15$$

$$10 = p(e)_{Corrected} * 0.85 + p(e)_{Corrected} * 0.165 = p(e)_{Corrected} * 1.015$$

$$p(e)_{Corrected} = 9.852$$

The general equation can be simplified to:

$$p(e)_{Corrected} = \frac{p(e)_{Observed}}{1 + f_{EPSS} * \propto_{EPSS}}$$

Again, substituting in the example values:

$$p(e)_{Corrected} = \frac{10}{1 + 0.15 * 0.1} = \frac{10}{1 + 0.015} = \frac{10}{1.015} = 9.852$$

EPSS was implemented first during the 2021 fire season. Therefore, only event counts for the 2021 and 2022 fires seasons are adjusted for EPSS impacts. Event counts for the 2015 through 2020 are used as observed. Therefore, the overall v4 impact for EPSS impact is minor. EPSS impact will become more important for future models as new fire season data is added to the training data sets.

3.4 Training Target Data Sets

The Failures/Outage and Ignition event data used to train and validate the event probability models is produced from the following PG&E data sets:

Table 1 - Event Target Data Set Sources

Data Set	Description	Source
Outages/Forced Outages	Automated detection and documentation of outages that interrupt power to at least one customer.	Integrated Logging Information System (ILIS)
Hazards/Damages	Issues classified as potential hazards or actual equipment damage identified during post-PSPS event inspections.	Post-PSPS Inspection Data
Ignitions	Ignitions with no corresponding ILIS outage are treated as a failure/outage for model development	Electronic Ignitions Database
Emergency A-tags	A-tags with an Outage Information System (OIS) number not included in any other data set above are treated as a failure/outage event for model development.	SAP Notifications

The *Table 1* source event data sets were selected to provide as many failure or fault events as possible representing the modeled failure drivers with accurate event date and time data. The events need an accurate date and time to associate the event with the weather data for the ignition modeling. For this reason, pre-existing failures identified during inspection were not used.

Events used for modeling were filtered using the following criteria:

- Occurred during wildfire season.
- Occurred during or after 2015 when improved ignition recording was initiated.
- Event has a recorded latitude and longitude, a requirement for location-based pixel models.
- Restricted, where known, to overhead assets.
    - Some non-overhead events likely remain in the target data sets due to ambiguous labeling.

For each qualified event, four attributes are extracted from the source data sets to assign the event to the appropriate Equipment Asset or Contact From Object event probability model:

Table 2 - Event Categorization Attributes

Field	Description
Cause	Primary failure cause
Sub-Cause	Failure cause detail
Equipment Type	Asset involved in event
Voltage Category	Primary or secondary system

Table 3 summarizes how categorical attributes are used to assign events to event probability models:

3.5 Probability of Failure/Outage Models

The probability of failure and outage models predict the likelihood of an electrical grid asset failure or outage during a fire season. This section will describe each of the probability of failure models in detail and has been organized by the two broad types of failure model types, Equipment Asset and Contact From Object, which include:

- Equipment Asset models
  - Capacitor Banks
  - Dynamic Protective Devices (DPD)
  - Fuses
  - Primary Conductors
  - Secondary Conductors
  - Transformers
  - Voltage Regulators
  - Other Equipment
- Contact From Object models
  - Animal
  - Third-Party
  - Vegetation

3.5.1 Equipment Asset Models

The DEPM v4 equipment asset models scale the methodology used for the v3 support structure and transformer models to all but two asset models. The methodology tracks assets over the modeling period using historical snapshots of EDGIS asset data sets. Using historical data sets enables identification of a failed asset even if the asset was removed from service due to the failure. In turn, the attributes of a failed asset can be linked to its failure and used to train an asset model.

The v4 asset-specific models are a significant upgrade over the v3 pixel-based models. A common issue with pixel model data is that a pixel often contained multiple assets, making it difficult to understand precisely which asset was most at risk for failure. The v4 asset-specific models, therefore, are more useful for developing targeted asset management and asset work plans.

Table 4 - Equipment Asset Model Summary

Equipment Asset Event Model	Wildfire Season (mean values)			v4 Probability of Failure		v3 Probability of Failure
	Failures	Ignitions	Ignitions per Failure	Test AUC	Test Average Precision	Test AUC
Capacitor Bank	45	13	0.29	0.52	0.0049	n/a
DPD – Dynamic Protection Device	44	5.3	0.12	0.51	0.0054	n/a

Other Equipment	7722	29	0.003	0.76	0.0002	0.755

3.5.1.1 Capacitor Bank Model

Parallel installed capacitor banks, also called shunt capacitors, provide power factor correction on longer distribution circuits. They respond to voltage levels by switching in or out of service to boost or buck (reduce) line voltage. Due to the stresses from switching, capacitor Banks have the potential to fail catastrophically with an explosion that leads to an ignition that is both a wildfire and a public safety concern. As documented in *Table 4*, Capacitor Banks have the highest historical ignition to failure rate of all modeled distribution assets.

3.5.1.1.1 Key Developments

Capacitor bank and voltage regulator failure events were bundled together in a common spatial model for v3 using the MaxEnt algorithm. For v4, capacitor bank and voltage regulator failure events are modeled separately. Additionally, the v3 spatial model approach was replaced with a time-series model for v4.

The time-series model upgrade was enabled by establishing capacitor bank asset history back to 2016 through an examination of annual snapshots of EDGIS asset data. By examining the historical asset data, failures could be traced back to specific equipment in service at the time of failure and the actual attributes of the failed equipment could in turn be used to train the model.

During model development there were some features that were explored, but not included as covariates in the final model:

- Open tags
- Seasonal meteorology data

3.5.1.1.2 Performance

Capacitor banks were the most challenging equipment asset type to model for v4. Despite training data quality improvements and multiple rounds of new feature experimentation, model performance, as shown in *Figure 4* and *Figure 5*, was very poor, with an AUC of only 0.52. In subsequent discussions with SMEs, it was noted that capacitor banks are regularly inspected every year and therefore do not have a replacement backlog or a maintenance tag backlog. The working theory is that the proactive maintenance of capacitor banks makes the failures more challenging to predict.

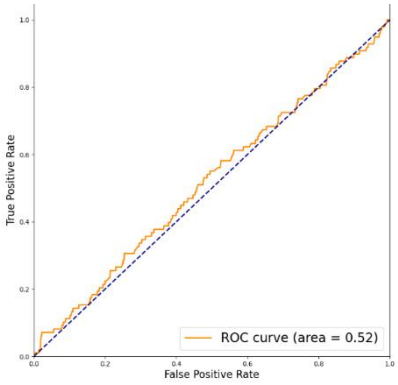

Figure 4 – Capacitor Bank ROC Curve

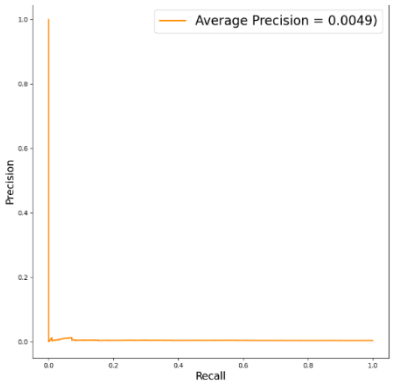

Figure 5 - Capacitor Bank Precision-Recall Curve

3.5.1.1.3 Model Data

The scope of the model was limited to overhead capacitor banks on the distribution system. On average, there were 45 capacitor bank failures and 13 ignitions during wildfire season between 2016 – 2022.

Table 5 – Capacitor Bank Event Summary

Capacitor Bank Event Counts				
	Training Data		Testing Data	
Year	Failures	Ignitions	Failures	Ignitions
2016	28	9	16	4
2017	29	10	19	4
2018	28	8	10	3
2019	27	13	10	2
2020	28	6	15	5
2021	38	8	19	4
2022	37	12	9	3
Totals	**215**	**66**	**98**	**25**

3.5.1.1.4 Algorithm Selection

During development, capacitor bank failure models were built using SparkML's Random Forest, Gradient Boosted Trees, Logistic Regression, and the Spark version of XGBoost. Ultimately, the XGBoost algorithm was selected for its predictive performance, built-in feature selection, ability to handle missing values, and speedy computation time.

3.5.1.1.5 Covariate Selection

Many capacitor bank attributes were tested as features in the model, but none showed major performance gains. *Figure 6* presents the total gains feature importance for the capacitor bank model. Top features include estimated asset age, asset total kVAR capacity, current transformer (CT) rating, supervisory control indicator (remote operation status), switch type, and asset switched off in the winter status.

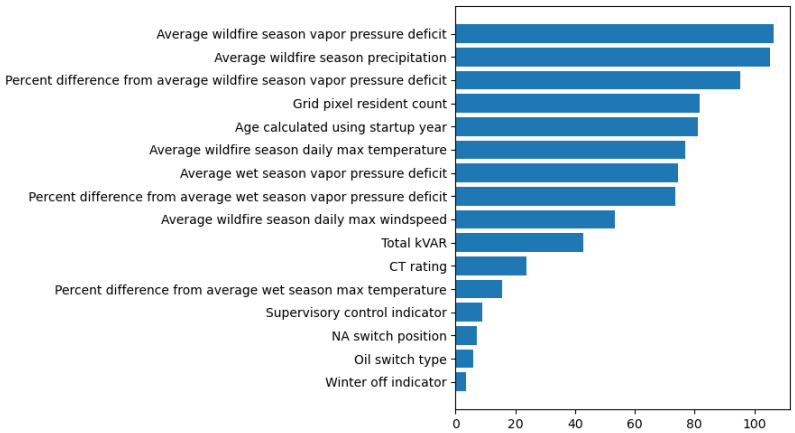

Figure 6 - Capacitor Bank Feature Importance

Figure 7 shows the SHAP plot for the capacitor bank model. Interpreting the plot, model prediction relationships can be understood and validated. For the capacitor banks, higher probability of failure was found to be correlated with:

- High max temperature values
- Low wildfire season precipitation
- High kVAR values
- Low vapor pressure deficits

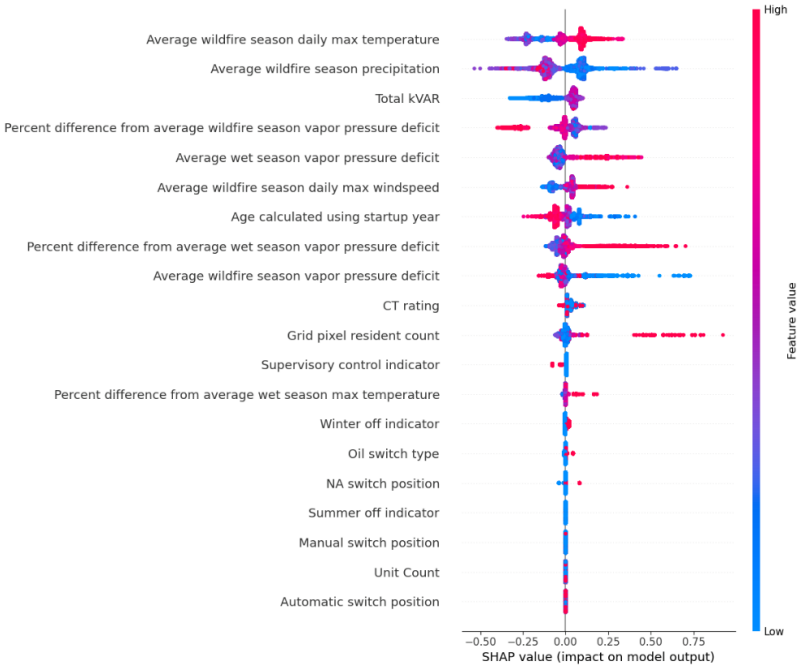

Figure 7 - Capacitor Bank SHAP Plot

3.5.1.1.6 Limitations and Opportunities

Capacitor banks have a very high ignition to failure rate. Therefore, it will be important to improve on the poor performance of the v4 probability of failure prediction model. Since the capacitor bank equipment attributes were not sufficient for predicting capacitor banks failures, new datasets will need to be investigated with SMEs. Switching history, historical loading, and distribution planning load flow (CYME) datasets are recommended for feature engineering in the future. Revisiting failure pathways with SMEs and potential data quality issues for capacitor bank records could be beneficial as well. If the machine learning model continues to perform poorly, a physics-based first principles model will be investigated.

3.5.1.2 DPD Equipment Model

Dynamic Protection Devices (DPD), which include line reclosers and sectionalizers, help protect the distribution system by opening when a fault is detected and attempt to reclose to re-establish service for momentary faults. Examples of DPD equipment failures include when the device malfunctions or the actuator board or controls do not operate as expected in response to a fault.

3.5.1.2.1 Key Developments

DPD equipment, conductor, switch, and fuse events were bundled together in a common spatial model for v3 using the MaxEnt algorithm. For v4, DPD equipment was modeled separately from conductors, switches, and fuses. Additionally, the v3 spatial model approach was replaced with a time-series model for v4.

The time-series model upgrade was enabled by establishing DPD asset history back to 2016 through an examination of annual snapshots of EDGIS asset data. By examining the historical asset data, failures could be traced back to specific equipment in service at the time of failure and the actual attributes of the failed equipment could in turn be used to train the model.

During model development there were some features that were explored, but not included as covariates in the final model:

- Open tags
- Seasonal meteorology data

3.5.1.2.2 Performance

DPD Equipment was a challenging equipment asset type to model for v4. Despite training data quality improvements and multiple rounds of new feature experimentation, model performance, as shown in *Figure 8* and *Figure 9*, was very poor, with an AUC of only 0.51.

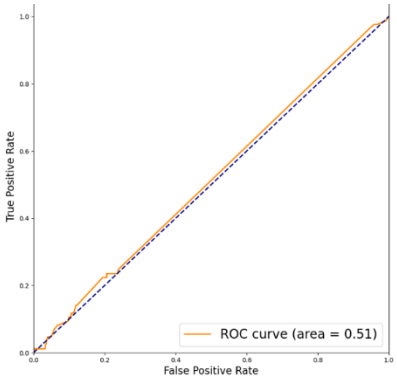

Figure 8 - DPD ROC Curve

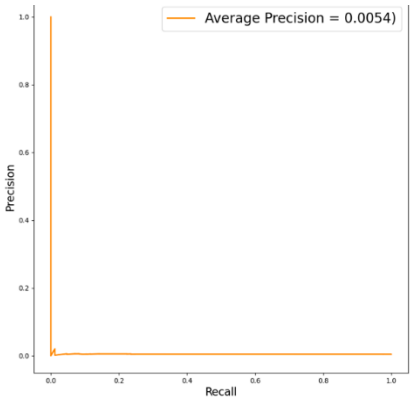

Figure 9 - DPD Precision-Recall Curve

3.5.1.2.3 Model Data

The scope of the model was limited to overhead DPD equipment on the distribution system. On average, there were 44 DPD failures and 5.3 ignitions during wildfire season between 2016 – 2022.

Table 6 - DPD Equipment Event Summary

DPD Event Counts				
	Training Data		Testing Data	
Year	Failures	Ignitions	Failures	Ignitions
2016	22	7	17	2
2017	33	2	12	1
2018	26	2	6	1
2019	43	8	18	4
2020	25	1	11	0
2021	34	7	8	2
2022	32	0	13	0
Totals	**215**	**27**	**85**	**10**

3.5.1.2.4 Algorithm Selection

During development DPD failure models were built using SparkML's Random Forest, Gradient Boosted Trees, Logistic Regression, and the Spark version of XGBoost. Ultimately, the XGBoost algorithm was selected for its predictive performance, built-in feature selection, ability to handle missing values, and speedy computation time.

3.5.1.2.5 Covariate Selection

Many DPD equipment attributes were tested as features in the model, with the relative humidity difference between the average wet season showing the most performance gains. *Figure 10* presents the total gains feature importance for the DPD equipment model. Equipment attributes experimented with during development included estimated asset age, fault duty, continuous current (CC) rating, maximum interrupting current, supervisory control indicator, bypass switch indicator, interrupting medium, device type, and open tags. Of these, the estimated asset age and fault duty were found to be meaningful additions to the model.

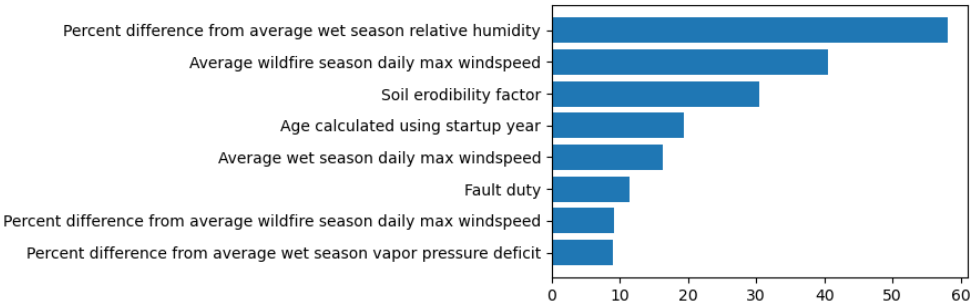

Figure 10 - DPD Feature Importance

Figure 11 shows the SHAP plot for the DPD equipment model. Interpreting the plot, model prediction relationships can be understood and validated. For the DPD equipment, higher probability of failure was found to be correlated with:

- High fire season max windspeed
- High wet season max windspeed
- Soil erodibility
- High estimated asset age

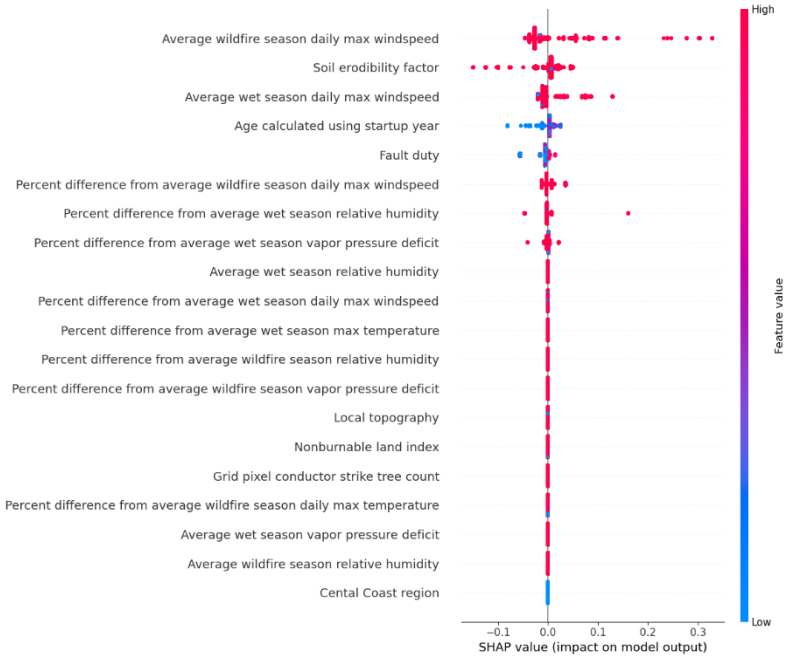

Figure 11 - DPD SHAP Plot

3.5.1.2.6 Limitations and Opportunities

Additional investigation in partnership with SMEs is needed to gain a deeper understanding of what causes DPD equipment to malfunction. This may help to identify new datasets and potential model features. Continuing DPD equipment record data quality improvements, additional failure event validation and consideration of separating out switch and bird guard related events could improve model performance.

3.5.1.3 Fuse Equipment Model

Fuses are electrical safety devices that can help protect the distribution system by preventing the flow of excessive electric current through the system.

3.5.1.3.1 Key Developments

DPD equipment, primary conductor, switch, and fuse events were bundled together in a common spatial model for v3 using the MaxEnt algorithm. For v4, fuses were modeled separately from conductors, DPDs, and switches. Additionally, the v3 spatial model approach was replaced with a time-series model for v4.

The time-series model upgrade was enabled by establishing fuse asset history back to 2016 through an examination of annual snapshots of Electrical Distribution GIS (EDGIS) asset data. By examining the historical asset data, failures could be traced back to specific equipment in service at the time of failure and the actual attributes of the failed equipment could in turn be used to train the model.

During model development there were some features that were explored, but not included as covariates in the final model:

- Open tags
- Seasonal meteorology data

3.5.1.3.2 Performance

The v4 Fuse failure model demonstrated moderately good model performance, as shown in *Figure 12* and *Figure 13*, with an AUC of 0.67.

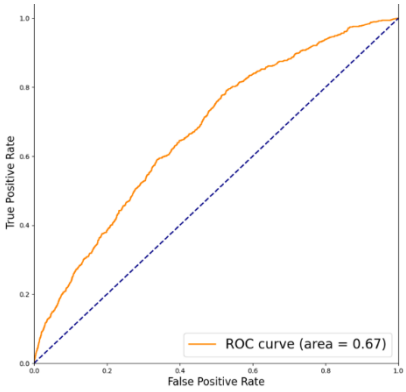

Figure 12 - Fuse ROC Curve

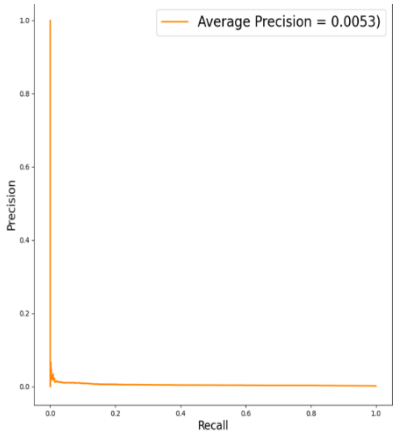

Figure 13 - Fuse Precision-Recall Curve

3.5.1.3.3 Model Data

The scope of the model was limited to overhead fuses on the distribution system. On average, there were 299 fuse failures and 20.7 ignitions during wildfire season between 2016 – 2022.

Table 7 - Fuse Equipment Event Summary

Fuse Event Counts				
	Training Data		Testing Data	
Year	Failures	Ignitions	Failures	Ignitions
2016	182	13	90	4
2017	223	26	104	13
2018	191	13	83	5
2019	184	16	93	9
2020	216	9	106	9
2021	203	14	94	5
2022	223	4	101	5
Totals	**1422**	**95**	**671**	**50**

3.5.1.3.4 Algorithm Selection

During development Fuse failure models were built using SparkML's Random Forest, Gradient Boosted Trees, Logistic Regression, and the Spark version of XGBoost. Ultimately, the XGBoost algorithm was selected for its predictive performance, built-in feature selection, ability to handle missing values, and speedy computation time.

3.5.1.3.5 Covariate Selection

Figure 14 presents the total gains top feature importance for the Fuse model performance. Top features include estimated fuse age, fuse link rating, corrosion zone status, average vapor pressure deficit, average relative humidity, and average operating voltage.

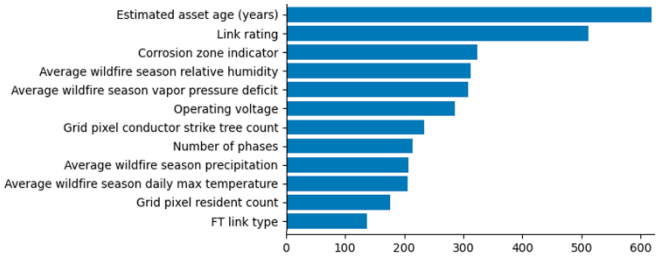

Figure 14 - Fuse Top Feature Importance

Other covariate features that moderately contribute to the Fuse model include:

- Percent difference from average wildfire season relative humidity
- Average wet season relative humidity
- Local topography
- Percent difference from average wet season max temperature
- Soil erodibility factor
- Percent difference from average wildfire season daily max temperature
- Percent difference from average wildfire season daily max windspeed
- Percent difference from average wildfire season daily vapor pressure deficit
- Average wet season vapor pressure deficit
- Percent difference from average wet season relative humidity
- Percent difference from average wet season daily max windspeed
- HFTD
- Complex device indicator
- Bypass switch indicator
- S&C manufacturer
- Percent difference from average wet season vapor pressure deficit

Figure 15 shows the SHAP plot for the Fuse model. Interpreting the plot, model prediction relationships can be understood and validated. For the Fuse equipment, higher probability of failure was found to be correlated with:

- High estimated fuse age
- Low link rating
- In corrosion zone
- Higher number of phases

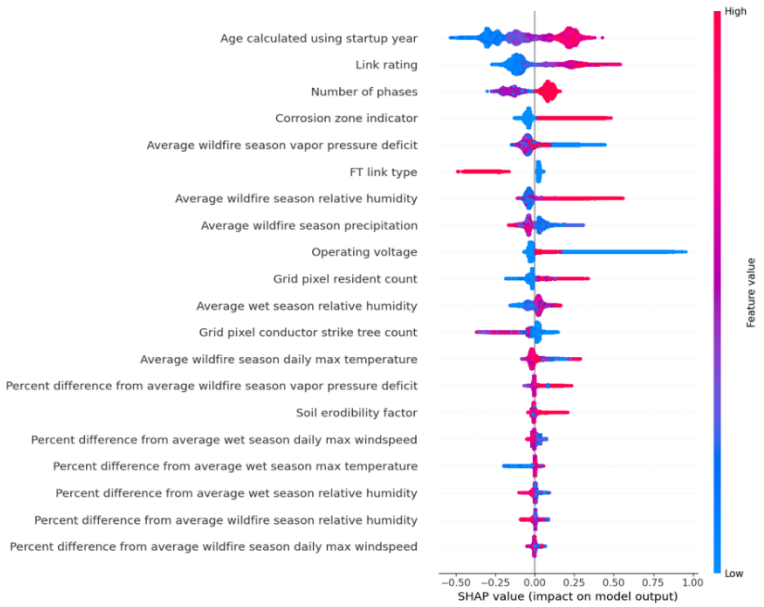

Figure 15 - Fuse SHAP Plot

3.5.1.3.6 Limitations and Opportunities

Future model development is expected to focus on SME collaboration to better understand why link rating and fuse age are so helpful for predicting fuse failures.

During v4 development, it was observed that a notable portion of failed fuses were not mapped in EDGIS until their year of failure. This observation will need to be followed up with EDGIS personnel to understand the current maturity of mapping fuses for the distribution system.

3.5.1.4 Primary Overhead Conductor Models

Primary overhead conductors play a crucial role in delivering electricity safely and reliably to customers. The primary conductors are the system spans of conductor phases that transport electricity from substations to distribution transformers.

Primary overhead conductor, DPD equipment, switch, and fuse events were bundled together in a common spatial model for v3 using the MaxEnt algorithm. For v4, Primary overhead conductor failures were modeled separately from fuses, DPDs, and switches. The v3 spatial model approach was replaced with a time-series model for v4 that estimates the likelihood of failure at the nearest pole for the 2023 wildfire season. In addition, the primary overhead conductor failures were separated and developed into three distinct causal models for v4:

- Line Slap – for line slap event failures
- Wire Down – for line to ground failures
- Other – jumper, riser and unknown cause failures

3.5.1.4.1 Primary Overhead Conductor – Line Slap

Primary overhead conductor line slap failures can occur from wind or fault current events that result in two conductor phases becoming physically close enough to cause arcing or sparking which could result in an ignition event. A line slap event can also cause annealing on the conductor which accelerates conductor deterioration and increase the future likelihood of a wire down event.

3.5.1.4.1.1 Key Developments

The Primary Overhead Conductor – Line Slap model was developed as a time-series model for v4, replacing the v3 spatial model for combined primary overhead conduct, DPD, fuse, and switch events.

The time-series model upgrade was enabled by establishing primary overhead conductor asset history back to 2016 through an examination of annual snapshots of Electrical Distribution GIS (EDGIS) asset data. By examining the historical asset data, line slap failures could be traced back to the nearest pole in service at the time of failure. Tracing conductor failures directly to conductor spans was infeasible as historically failure events are typically recorded at the pole.

Several features were explored during model development, including:

- CYME software fault duty analysis
- Observed splices
- Covered conductor status
- LiDAR span data
- Output from the Finite Element Analysis (FEA) model developed by PG&E's Applied Technology Services (ATS) covering:
  - Wind scenarios
  - Fault current scenarios
- Open repair tags
- Seasonal meteorology data

3.5.1.4.1.2 Performance

The new v4 line slap failure model demonstrated moderately good model performance, as shown in *Figure 16* and *Figure 17*, with an AUC of 0.68.

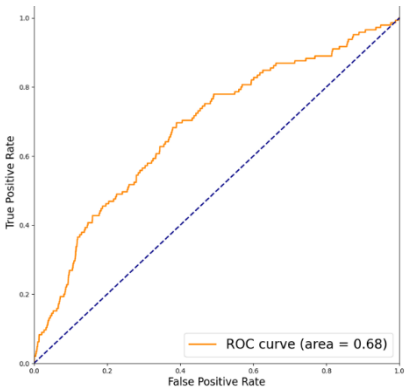

Figure 16 - Line Slap ROC Curve

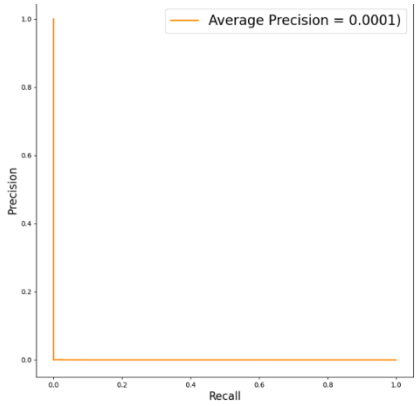

Figure 17 – Line Slap Precision-Recall Curve

3.5.1.4.1.3 Model Data

The scope of the model was limited to overhead conductor line slap events on the distribution system. On average, there were 108 line slap failures and 7.8 ignitions during wildfire season between 2019 – 2022.

Table 8 - Primary Conductor - Line Slap Event Counts

Line Slap Event Counts				
	Training Data		Testing Data	
Year	Failures	Ignitions	Failures	Ignitions
2019	70	3	47	0
2020	57	5	32	0
2021	107	15	45	5
2022	52	2	21	1
Totals	**286**	**25**	**145**	**6**

3.5.1.4.1.4 Algorithm Selection

During development Primary Overhead Conductor – Line Slap models were built using SparkML's Random Forest, Gradient Boosted Trees, Logistic Regression, and the Spark version of XGBoost. Ultimately, the XGBoost algorithm was selected for its predictive performance, built-in feature selection, ability to handle missing values, and speedy computation time.

3.5.1.4.1.5 Covariate Selection

Figure 18 presents the total gains top feature importance for the Primary Conductor – Line Slap model performance. Top features include conductor count, conductor length, max conductor weight, minimum conductor cross sectional area, pole height, and wind speed.

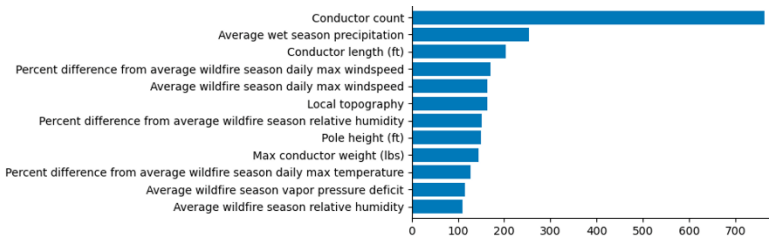

Figure 18 - Primary Condcutor - Line Slap Top Feature Importance

Other covariate features that moderately contribute to the Line Slap model include:

- Grid pixel resident count
- Percent difference from average wet season daily max windspeed
- Percent difference from average wet season vapor pressure deficit
- Average wildfire season daily max temperature
- Percent difference from average wildfire season vapor pressure deficit
- ATS FEA 3000A fault line slap risk
- Average wet season vapor pressure deficit
- Conductor max sag
- Min conductor cross section area
- Grid pixel conductor strike tree count
- Max conductor ultimate strength
- Soil erodibility factor
- Percent difference from average wet season max temperature
- Asset age
- Conductor spacing
- Percent difference from average wet season relative humidity
- Pole elevation
- Average wet season relative humidity
- ATS FEA 60-90 mph wind line slap risk
- Operating voltage
- CYME software fault duty analysis
- Triangular construction type

Figure 19 shows the SHAP plot for the Line Slap model. Interpreting the plot, model prediction relationships can be understood and validated. For the Line Slap cause, higher probability of failure was found to be correlated with:

- Lower conductor phase distances during high winds (FEA prediction)
- Higher conductor count
- Higher conductor max sag
- Higher conductor length
- Pole height
- Higher wet season precipitation

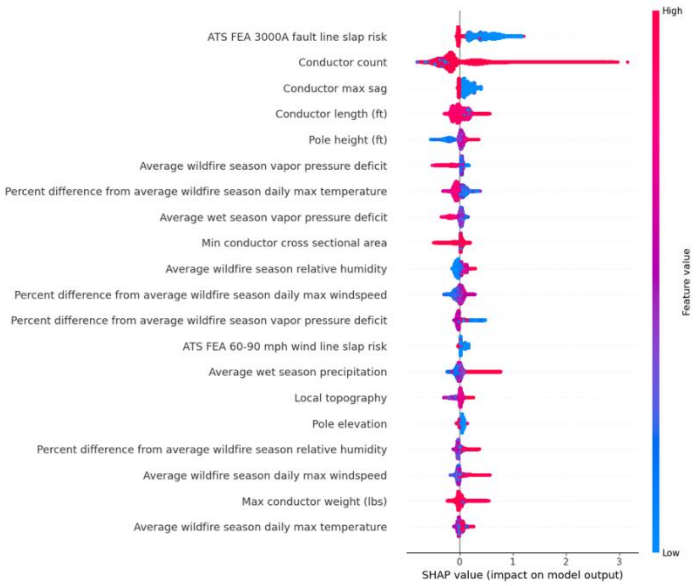

Figure 19 - Primary Conductor - Line Slap SHAP Plot

3.5.1.4.1.6 Limitations and Opportunities

Several initiatives could be pursued to improve the Line Slap model performance for future releases. Several new datasets were acquired during line slap model development. Therefore, another round of data cleanup and feature engineering would likely yield performance gains. Likewise, further review of historical primary conductor event records could identify additional line slap events to use for model training. Identifying additional training events could have a significant performance impact as the line slap event sample size is small in comparison to other primary conductor failure modes. Finally, additional feature engineering with meteorological data, especially wind gusts, could be explored.

3.5.1.4.2 Primary Overhead Conductor – Wire Down

Primary overhead conductor wire down failures are events where a primary wire has fallen or is no longer properly secured. Wire down events can be caused by equipment issues such as the improper installation of a conductor, a connector, or a splice and be degradation issues such as corrosion.

Note that object contacts that result in a wire down event are ***not*** included in the primary overhead conductor wire down model. All contact events are assigned to one of the Contact From Object models as described in Section *3.5.2*.

3.5.1.4.2.1 Key Developments

The Primary Overhead Conductor – Wire Down model was developed as a time-series model for v4, replacing the v3 spatial model for combined primary overhead conductor, DPD, fuse, and switch events.

The time-series model upgrade was enabled by establishing primary overhead conductor asset history back to 2016 through an examination of annual snapshots of Electrical Distribution GIS (EDGIS) asset data. By examining the historical asset data, wire down failures could be traced back to the nearest pole in service at the time of failure. Tracing conductor failures directly to conductor spans was infeasible as historically failure events are typically recorded at the pole.

Several features were explored during model development, including:

- CYME software fault duty analysis
- Observed splices
- Covered conductor status
- LiDAR span data
- Output from the Finite Element Analysis (FEA) model developed by PG&E's Applied Technology Services (ATS) covering:
  - Wind scenarios
  - Fault current scenarios
- Open repair tags
- Seasonal meteorology data

3.5.1.4.2.2 Performance

The new v4 wire down failure model demonstrated very good model performance, as shown in *Figure 20* and *Figure 21*, with an AUC of 0.76.

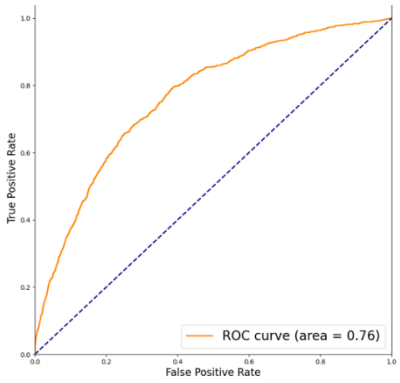

Figure 20 - Wire Down ROC Curve

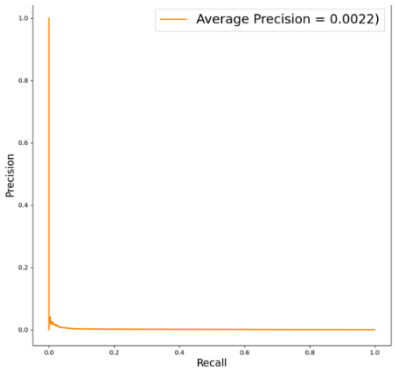

Figure 21 - Wire Down Precision-Recall Curve

3.5.1.4.2.3 Model Data

The scope of the model was limited to overhead conductor wired down events on the distribution system that were not caused by object contact. On average, there were 1005 wire down failures and 70 ignitions during wildfire season between 2019 – 2022.

Table 9 - Primary Conductor - Wire Down Event Counts

Wire Down Event Counts				
	Training Data		Testing Data	
Year	Failures	Ignitions	Failures	Ignitions
2019	687	42	224	18
2020	649	59	211	18
2021	887	54	311	23
2022	799	50	250	17
Totals	**3022**	**205**	**996**	**76**

3.5.1.4.2.4 Algorithm Selection

Primary conductor wire down events were modeled using SparkML's Random Forest, Gradient Boosted Trees and the spark version of XGBoost. Ultimately, the XGBoost algorithm was selected for its predictive performance, built-in feature selection, ability to handle missing values, and speedy computation time.

3.5.1.4.2.5 Covariate Selection

Figure 22 presents the total gains top feature importance for the Primary Conductor – Wire Down model performance. Top features include conductor count, non-burnable land index, conductor length, max conductor weight, minimum conductor cross sectional area, and height.

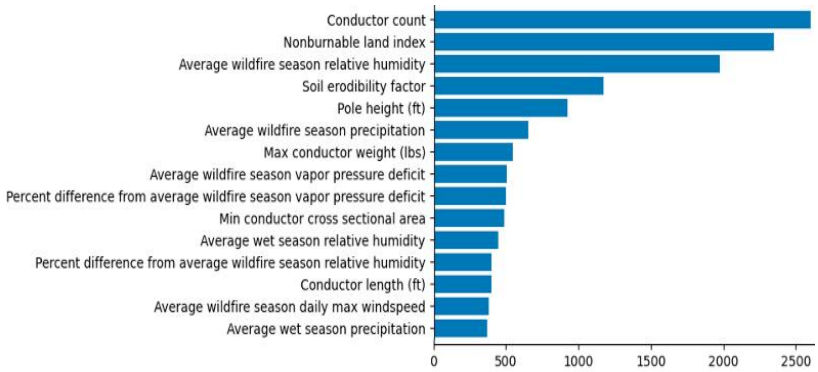

Figure 22 - Primary Conductor - Wire Down Top Feature Importance

Other covariate features that moderately contribute to the Wire Down model include:

- Percent difference from average wildfire season daily max temperature
- Average wet season vapor pressure deficit
- Asset age
- Average wildfire season daily max temperature
- Average wet season daily max temperature
- Coastal indicator
- Percent difference from average wildfire season daily max windspeed
- Max conductor ultimate strength
- Grid pixel conductor strike tree count
- Corrosion zone indicator
- ATS FEA 3000A fault line slap risk
- Percent difference from average wet season max temperature
- Conductor max sag
- Percent difference from average wet season relative humidity
- Percent difference from average wet season daily max windspeed
- Local topography
- Percent difference from average wet season vapor pressure deficit
- CYME software fault duty analysis
- ATS FEA 60-90 mph wind line slap risk
- Operating voltage
- Open tag indicator
- Pole elevation
- Splice observed indicator

Figure 23 shows the SHAP plot for the Wire Down model. Interpreting the plot, model prediction relationships can be understood and validated. For the wire down cause, higher probability of failure was found to be correlated with:

- Higher conductor counts
- Fire season humidity, probably as a proxy for coastal areas linked to corrosion.
- Higher pole heights
- Older conductor ages

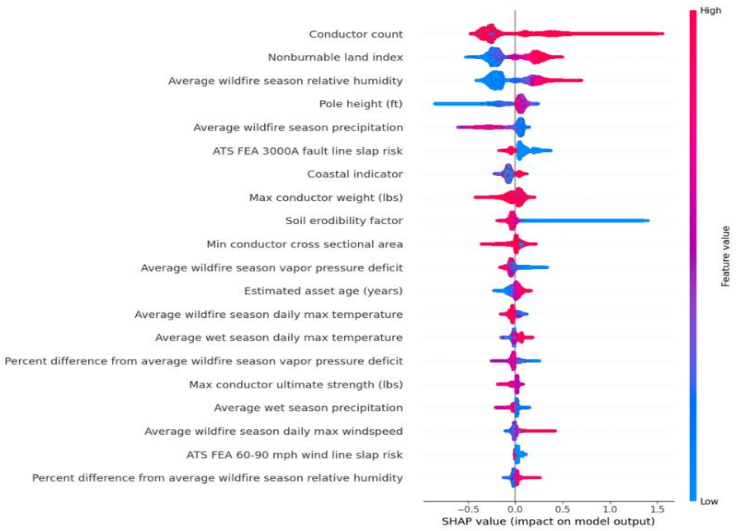

Figure 23 - Primary Conductor - Wire Down SHAP Plot

3.5.1.4.2.6 Limitations and Opportunities

Several initiatives could be pursued to improve the Wire Down model performance for future releases. Several new datasets were acquired during wire down model development. Therefore, another round of data cleanup and feature engineering would likely yield additional performance gains. Likewise, further review of historical primary conductor event records could identify additional wire down events to use for model training. Identifying additional training events could help improve model precision. Finally, additional feature engineering with meteorological data, especially identify areas prone to corrosion, could be explored.

3.5.1.4.3 Primary Conductor – Other

The Primary Conductor – Other model is developed using conductor failures that are not classified as line slap or wired down. Typically, these events include equipment issues related to risers and jumpers as well as conductor-related incidents where the source of failure may have been difficult to identify.

3.5.1.4.3.1 Key Developments

The Primary Overhead Conductor – Other model was developed as a time-series model for v4, replacing the v3 spatial model for combined primary overhead conductor, DPD, fuse, and switch events.

The time-series model upgrade was enabled by establishing primary overhead conductor asset history back to 2016 through an examination of annual snapshots of Electrical Distribution GIS (EDGIS) asset data. By examining the historical asset data, wire down failures could be traced back to the nearest pole in service at the time of failure. Tracing conductor failures directly to conductor spans was infeasible as historically failure events are typically recorded at the pole.

Several features were explored during model development, including:

- CYME software fault duty analysis
- Observed splices
- Covered conductor status
- LiDAR span data
- Output from the Finite Element Analysis (FEA) model developed by PG&E's Applied Technology Services (ATS) covering:
  - Wind scenarios
  - Fault current scenarios
- Open repair tags
- Seasonal meteorology data

3.5.1.4.3.2 Performance

The new v4 other failure model demonstrated very good model performance, as shown in *Figure 24* and *Figure 25*, with an AUC of 0.76.

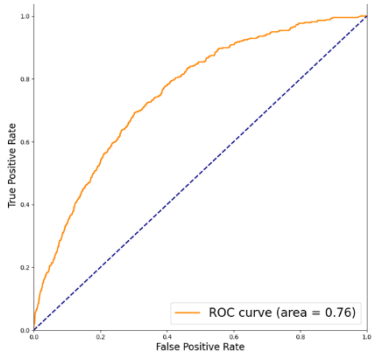

Figure 24 - Primary Conductor - Other ROC Curve

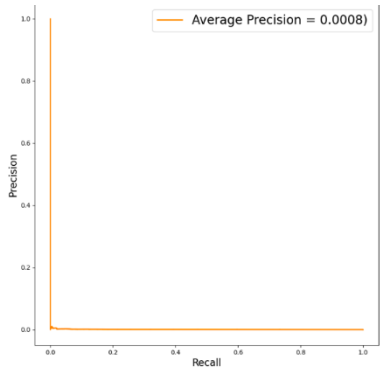

Figure 25 - Primary Conductor - Other Precision-Recall Curve

3.5.1.4.3.3 Model Data

The scope of the model was limited to primary overhead conductor events on the distribution system that were not included in either the Line Slap or Wire Down models. On average, there were 438 other event failures and 23 ignitions during wildfire season between 2019 – 2022.

Table 10 - Primary Conductor - Other Equipment Event Counts

Other Event Counts				
	Training Data		Testing Data	
Year	Failures	Ignitions	Failures	Ignitions
2019	296	20	93	6
2020	325	25	111	4
2021	369	14	113	5
2022	323	13	121	5
Totals	**1313**	**72**	**438**	**20**

3.5.1.4.3.4 Algorithm Selection

Primary conductor wire down events were modeled using SparkML's Random Forest, Gradient Boosted Trees and the spark version of XGBoost. Ultimately, the XGBoost algorithm was selected for its predictive performance, built-in feature selection, ability to handle missing values, and speedy computation time.

3.5.1.4.3.5 Covariate Selection

Figure 26 presents the total gains top feature importance for the Primary Conductor – Other model performance. Top features include conductor count, non-burnable land index, conductor length, soil erodibility factor, humidity, precipitation, and pole height.

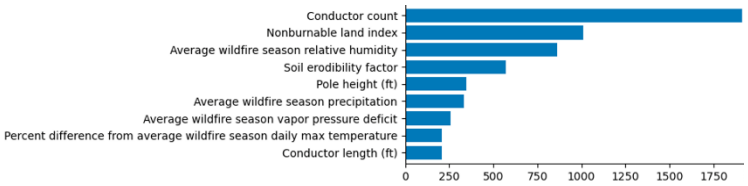

Figure 26 - Primary Conductor - Other Top Feature Importance

Other covariate features that moderately contribute to the Primary Conductor – Other model include:

- Max conductor weight
- Percent difference from average wildfire season vapor pressure deficit
- Average wildfire season daily max windspeed
- Average wet season precipitation
- Asset age
- Percent difference from average wet season relative humidity
- Coastal indicator
- Percent difference from average wet season vapor pressure deficit
- Grid pixel conductor strike tree count
- Average wet season relative humidity
- Average wildfire season daily max temperature
- Percent difference from average wet season max temperature
- Percent difference from average wildfire season daily max windspeed
- Average wet season vapor pressure deficit
- Percent difference from average wildfire season relative humidity
- Local topography
- Percent difference from average wet season daily max windspeed
- Conductor max sag
- Min conductor cross sectional area
- Average wet season daily max temperature
- Triangular construction type
- CYME software fault duty analysis
- Neutral indicator

Figure 27 shows the SHAP plot for the Primary Conductor - Other model. Interpreting the plot, model prediction relationships can be understood and validated. For the other conductor cause, higher probability of failure was found to be correlated with:

- Higher conductor counts
- Non-burnable index, probably as a proxy for urban/non-urban areas
- Fire season humidity, probably as a proxy for coastal areas linked to corrosion.
- Coastal indicator
- Older conductor ages
- Lower fire season vapor pressure deficits

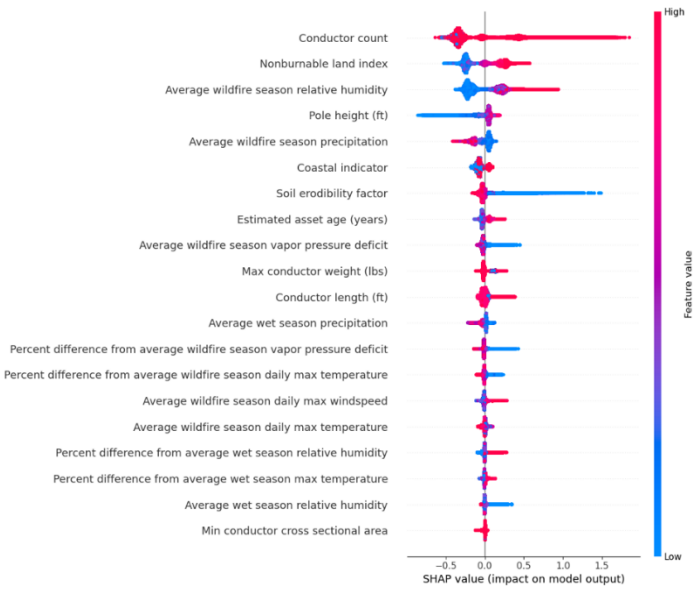

Figure 27 - Primary Conductor - Other SHAP PLot

3.5.1.4.3.6 Limitations and Opportunities

Several initiatives could be pursued to improve the Primary Conductor - Other model performance for future releases. Several new datasets were acquired during model development. Therefore, another round of data cleanup and feature engineering would likely yield performance gains. Likewise, further review of historical primary conductor event records could identify and remove line slap and wire down events to use for model training. Cleaning out line slap and wire down events could in turn help improve Other model performance. Finally, additional feature engineering with meteorological data, especially identify areas prone to corrosion, could be explored.

3.5.1.5 Secondary Conductor Model

The Secondary Conductor equipment model uses historical failure events and spatial environmental data to model future fire season outage probabilities of low voltage secondary conductor assets.

3.5.1.5.1 Key Developments

The Secondary Conductor v4 model is a refresh of the v3 model. The only significant update was the addition of 2023 failures to the event training dataset.

3.5.1.5.2 Performance

The v4 Secondary Conductor outage model demonstrated good model performance with an AUC of 0.78 as shown in *Figure 28*. This was an improvement from the v3 AUC of 0.70

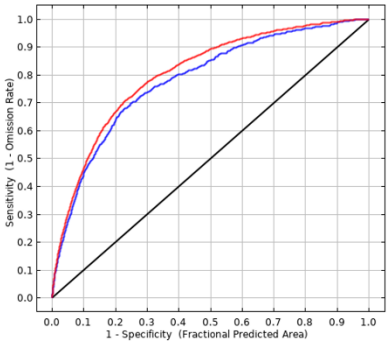

Figure 28 - Secondary Conductor ROC Curve

3.5.1.5.3 Model Data

Table 11 presents a summary of event counts used for v4 development:

Table 11 - Secondary Conductor Event Summary

Event Type	Value
Outage Count	3318
Ignition Count	223
Ignitions Per Outage	0.0672

3.5.1.5.4 Algorithm Selection

The MaxEnt algorithm, which was used for v3, was retained for v4 due to its ability to analyze presence only events and preserve spatial interactions during model optimization.

3.5.1.5.5 Covariate Selection

Figure 29 presents the total gains feature importance that account for 95% of the Secondary Conductor model performance. Top features include strike tree counts, the impervious and non-burnable land indices that indicate urban environments, and strike tree height.

There are numerous additional covariate features that marginally contribute to the Other

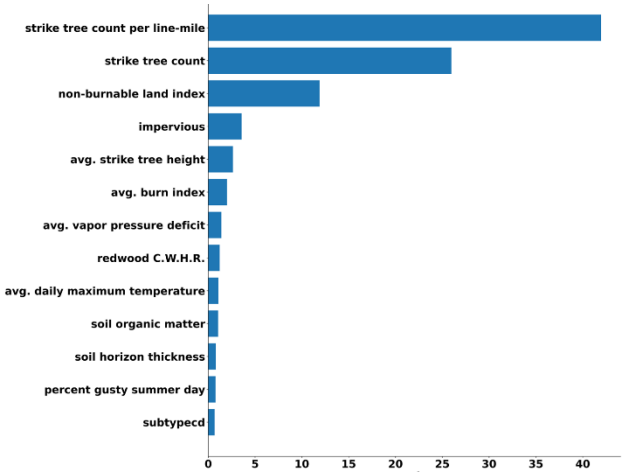

Figure 29 - Secondary Conductor Top Feature Performance

Equipment model, accounting for the remaining 5% of model performance:

- eucalyptus CWHR
- maximum strike tree height
- maximum wind speed
- avg. 100-hr fuels
- windy summer day percentage
- tier-2
- valley oak woodland CWHR
- minimum strike tree height
- montane hardwood CWHR
- soil slope
- available soil water capacity
- soil permeability
- coastal oak woodland CWHR
- annual soil flood frequency
- local topography
- canopy density
- tree species
- eastside pine CWHR
- ponderosa pine CWHR
- is soil hydric
- soil clay content
- operating voltage
- montane hardwood CWHR
- blue oak woodland CWHR
- avg. specific humidity
- soil hydro-group
- avg. precipitation
- aspen CWHR
- montane riparian CWHR
- closed cone pine cypress CWHR
- avg. wind speed
- avg. energy release

3.5.1.5.6 Limitations and Opportunities

Alternative deep learning algorithms such as Recurrent Neural Networks and Transformers are being investigated for future releases to improve the Secondary Conductor model with temporal dependencies in addition to the modeled spatial dependencies.

3.5.1.6 Support Structure Model

Support Structures physically support and maintain the alignment and positioning of distribution asset infrastructure. Support structure failures were modeled by asset for v3 using a time series algorithm, though the asset results were mapped to pixels for aggregation and compositing to circuit segments. The two causal failure models were refreshed for v4:

- Equipment Failure – any structural failure of a pole or its crossarms
- Electrical Failure – insulator or crossarm contamination, tracking, and other electrical issues

Similar to v3, the v4 scope of the Support Structure models is limited to wood poles only.

3.5.1.6.1 Support Structure – Electrical Failure Model

Support Structure electrical failures often result from contamination on crossarms and insulators that eventually leads to tracking and arcing particularly for older and cracked insulators. The failures frequently result in an ignition, but not necessarily an outage, making failures both a wildfire and a public safety concern. Fortunately, these ignitions are typically contained to the top of the pole and do not result in a fire large enough to be CPUC-reportable.

3.5.1.6.1.1 Key Developments

Key developments for the Support Structure – Electrical Failure model include:

- The electrical failure events training data set used for v3, which covered fire season events from 2016 through 2021, was updated to include the 2022 failure events for v4 model development.
- Seasonal meteorology attributes were developed as new model features for v4. Otherwise, the v4 model was mostly a refresh of the v3 model with updated failures and attributes data.
- Electrical failure probabilities and risks are estimated at the asset level for v4 and subsequently aggregated and composited through asset to conductor relationships to produce more accurate v4 circuit segment failure probability and risk values. While electrical failures were also modeled at an asset level for v3, the asset level results were converted into spatial pixel values for circuit segment aggregation and compositing. The v3 spatial aggregation frequently resulted in the electrical failure probability and risk for any given support structure being shared equally with every conductor asset that occupied the same pixel as the support structure. As a result, the real failure probability and risk values for multiple conductors passing through a single spatial pixel could be higher or lower than the reported aggregated values.

3.5.1.6.1.2 Performance

The new v4 Support Structure – Electrical failure model demonstrated very good model performance, as shown in *Figure 30* and *Figure 31*, with an AUC of 0.76.

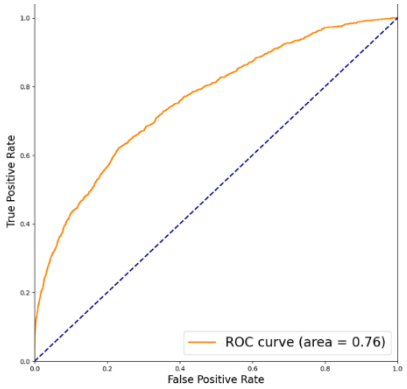

Figure 30 - Support Structure - Electrical ROC Curve

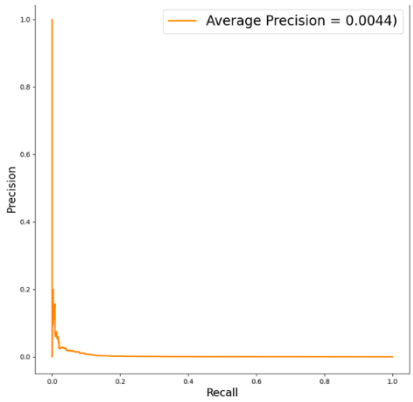

Figure 31 - Support Structure - Electrical Precision-Recall Curve

3.5.1.6.1.3 Model Data

The scope of the model was limited to wooden support structures on the distribution system. On average, there were 467 electrical support structure failures and 103 ignitions during wildfire season between 2016 – 2022.

Table 12 - Support Structure - Electrical Event Summary

Electrical Event Counts				
	Training Data		Testing Data	
Year	Failures	Ignitions	Failures	Ignitions
2016	266	24	110	9
2017	306	19	108	8
2018	284	25	101	12
2019	241	18	91	10
2020	278	40	117	17
2021	632	272	270	109
2022	322	102	146	56
Totals	**2329**	**500**	**943**	**221**

3.5.1.6.1.4 Algorithm Selection

During development Support Structure – Electrical failure models were built using SparkML's Random Forest, Gradient Boosted Trees, Logistic Regression, and the Spark version of XGBoost. Ultimately, the XGBoost algorithm was selected for its predictive performance, built-in feature selection, ability to handle missing values, and speedy computation time.

3.5.1.6.1.5 Covariate Selection

Figure 32 presents the total gains top feature importance for the Support Structure – Electrical model performance. Top features include pole volume, age, humidity, non-burnable land index, precipitation, and tree count.

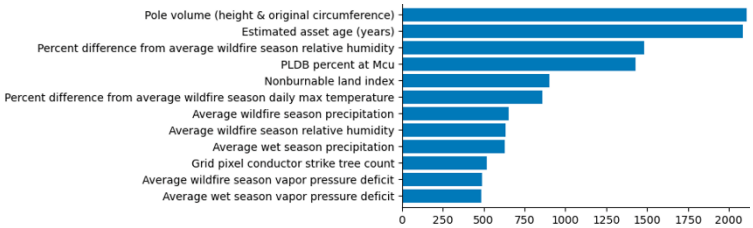

Figure 32 - Support Structure - Electrical Top Feature Importance

Other covariate features that moderately contribute to the Electrical failure model include:

- East Bay division
- Average wildfire season daily max windspeed
- Percent difference from average wet season relative humidity
- Percent difference from average wildfire season daily max windspeed
- Corrosion zone indicator
- Local topography
- Western Red Cedar pole species
- Percent difference from average wet season vapor pressure deficit
- Grid pixel resident count
- Soil annual flood frequency
- Average wet season relative humidity
- Average wildfire season daily max temperature
- Years since last PT&T inspection
- Mission division
- North Bay division
- Soil erodibility factor
- Percent difference from average wildfire season vapor pressure deficit
- Peninsula division
- Gas as original treatment type
- Sacramento division
- Unknown original treatment type
- San Francisco division
- Sierra division
- Not Available pole species
- Penta as original treatment type
- Central Coast division
- Pole attachment count

Figure 33 shows the SHAP plot for the Support Structure – Electrical failure model. Interpreting the plot, model prediction relationships can be understood and validated. For the support structures, higher probability of electrical failure was found to be correlated with:

- Low pole volumes
- High asset age
- Higher difference from average relative humidity

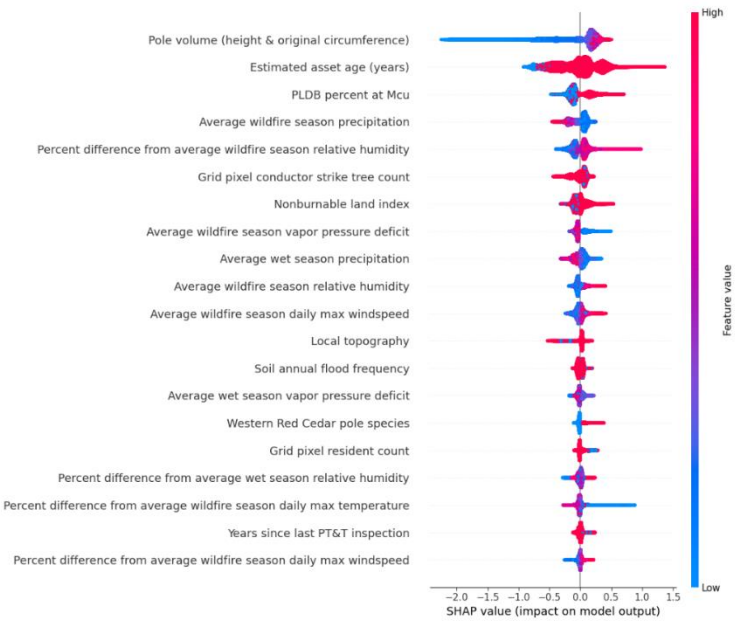

Figure 33- Support Structure - Electrical SHAP Plot

3.5.1.6.1.6 Limitations and Opportunities

As mentioned previously, the Support Structure model scope for v4 only considers wood poles. Work planners have frequently asked for the model coverage to be extended to include steel, concrete, and other types of poles as well.

Several initiatives could be pursued to improve the electrical failure model performance for future releases by exploring potential new model features, including:

- Large rain event identification – can wash away contamination
- Fog event identification – trigger tracking and arcing events
- Time-based air quality – predict contamination on insulators and crossarms
- Insulator type – identify insulators that are more prone to tracking and contamination

3.5.1.6.2 Support Structure – Structural Failure Model

Structural support structure failures occur when the support structure experiences a physical failure to the pole or its crossarm(s) and are often triggered by wind events. Structural failures have a low ignition to failure rate compared to other assets but often present a significant public safety issue. Typically, structural failures are the result of a pole ageing or decaying to the point where it can no longer carry its overhead equipment load. Decay is often accelerated when there is cycling between wet and dry soil in the subsurface portion of the pole.

3.5.1.6.2.1 Key Developments

Key developments for the Support Structure – Structural Failure model include:

- The structural failure events training data set used for v3, which covered fire season events from 2016 through 2021, was updated to include the 2022 failure events for v4 model development.
- Seasonal meteorology attributes were developed as new model features for v4. Otherwise, the v4 model was mostly a refresh of the v3 model with updated failures and attributes data.
- Structural failure probabilities and risks are estimated at the asset level for v4 and subsequently aggregated and composited through asset to conductor relationships to produce more accurate v4 circuit segment failure probability and risk values. While structural failures were also modeled at an asset level for v3, the asset level results were converted into spatial pixel values for circuit segment aggregation and compositing. The v3 spatial aggregation frequently resulted in the structural failure probability and risk for any given support structure being shared equally with every conductor asset that occupied the same pixel as the support structure. As a result, the real failure probability and risk values for multiple conductors passing through a single spatial pixel could be higher or lower than the reported aggregated values.

3.5.1.6.2.2 Performance

The new v4 Support Structure – Structural failure model demonstrated good model performance, as shown in *Figure 34* and *Figure 35*, with an AUC of 0.69.

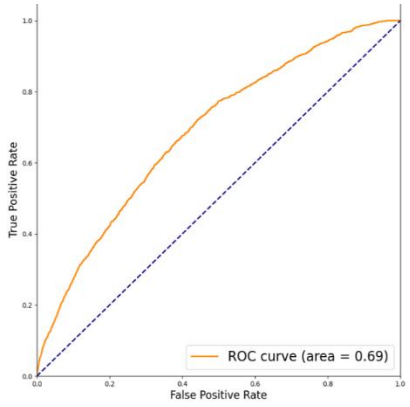

Figure 34 - Support Structure - Structural ROC Curve

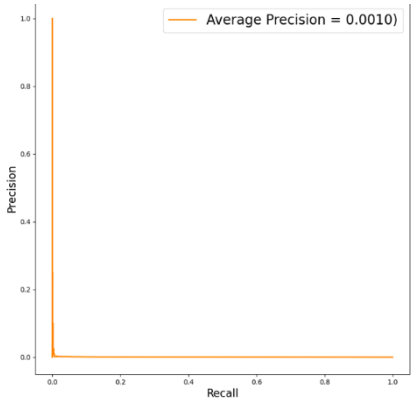

Figure 35 - Support Structure - Structural Precision-Recall Curve

3.5.1.6.2.3 Model Data

The scope of the model was limited to wooden support structures on the distribution system. On average, there were 667 structural support structure failures and 26.6 ignitions during wildfire season between 2016 – 2022.

Table 13 - Support Structure - Structural Event Summary

Structural Event Counts				
	Training Data		Testing Data	
Year	Failures	Ignitions	Failures	Ignitions
2016	299	3	132	2
2017	365	5	169	2
2018	414	58	183	22
2019	518	11	203	2
2020	418	20	230	11
2021	625	33	238	8
2022	622	5	255	4
Totals	**3261**	**135**	**1410**	**51**

3.5.1.6.2.4 Algorithm Selection

During development Support Structure – Structural failure models were built using SparkML's Random Forest, Gradient Boosted Trees, Logistic Regression, and the Spark version of XGBoost. Ultimately, the XGBoost algorithm was selected for its predictive performance, built-in feature selection, ability to handle missing values, and speedy computation time.

3.5.1.6.2.5 Covariate Selection

Figure 36 presents the total gains top feature importance for the Support Structure – Structural model performance. Top features include pole volume, pole age, pole strength, humidity, non-burnable land index, precipitation, and windspeed.

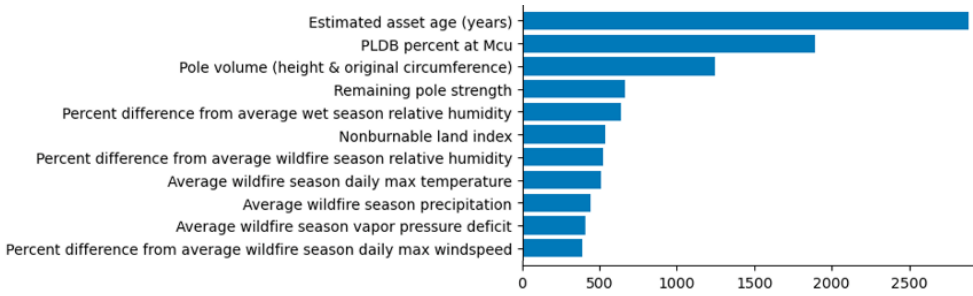

Figure 36 - Support Structure - Structural Top Feature Importance

Other covariate features that moderately contribute to the Structural failure model include:

- Average wildfire season relative humidity
- Difference between PT&T measured and original circumference
- Years since last PT&T inspection
- Percent difference from average wildfire season vapor pressure deficit
- Average wildfire season daily max windspeed
- Percent difference from average wildfire season daily max temperature
- Soil erodibility factor
- Average wet season relative humidity
- Average wet season precipitation
- Average wet season vapor pressure deficit
- Percent difference from average wet season vapor pressure deficit
- Unknown pole species
- Local topography * soil erodibility factor
- Open tag indicator
- Unknown original treatment type
- Grid pixel conductor strike tree count
- Soil annual flood frequency
- Local topography
- Penta as original treatment type
- Corrosion zone indicator

Figure 37 shows the SHAP plot for the Support Structure – Structural failure model. Interpreting the plot, model prediction relationships can be understood and validated. For the support structures, higher probability of structural failure was found to be correlated with:

- Low remaining pole strength
- Low percent at Mcu
- High asset age

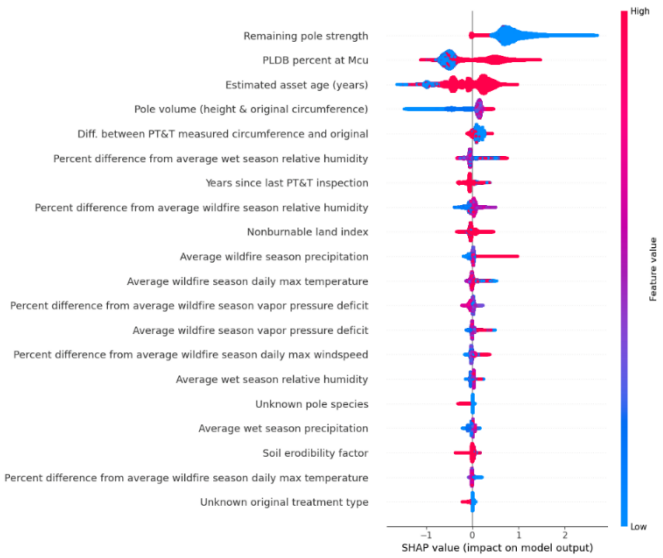

Figure 37 - Support Structure - Structural SHAP Plot

3.5.1.6.2.6 Limitations and Opportunities

As mentioned previously, the Support Structure model scope for v4 only considers wood poles. Work planners have frequently asked for the model coverage to be extended to include steel, concrete, and other types of poles as well.

Several initiatives could be pursued to improve the structural failure model performance for future releases by updating the model features, including:

- Additional data cleaning of the pole test and treat data set
- Testing removal of highly correlated features, especially meteorological features
- Additional data cleaning of structural failure events, with potential separation of:
  - Pole failure events
  - Crossarm failure events
  - Guywire failure events

3.5.1.7 Switch Equipment Model

Switches are devices that are used to control the flow of electricity in the network by opening or closing a section of a circuit. A switch can also serve to separate two different substation feeds. Switches are essential both for normal, emergency, and maintenance operations of the distribution network. Switches can fail from the loosening of hardware, causing operational problems of the switch, insulator breakage, or failed connectors. Switches have a relatively high ignition to failure rate when compared with other distribution assets.

3.5.1.7.1 Key Developments

Fuse, DPD equipment, primary conductor, and switch events were bundled together in a common spatial model for v3 using the MaxEnt algorithm. For v4, Switches were modeled separately from fuses, conductors, and DPDs. Additionally, the v3 spatial model approach was replaced with a time-series model for v4.

The time-series model upgrade was enabled by establishing switch asset history back to 2016 through an examination of annual snapshots of Electrical Distribution GIS (EDGIS) asset data. By examining the historical asset data, failures could be traced back to specific equipment in service at the time of failure and the actual attributes of the failed equipment could in turn be used to train the model.

During model development there were some features that were explored, but not included as covariates in the final model:

- Open tags
- Seasonal meteorology data

3.5.1.7.2 Performance

The v4 Switch failure model demonstrated a moderately good model performance, as shown in *Figure 38* and *Figure 39*, with an AUC of 0.67.

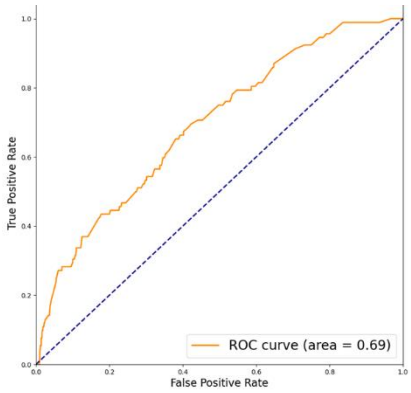

Figure 38 - Switch ROC Curve

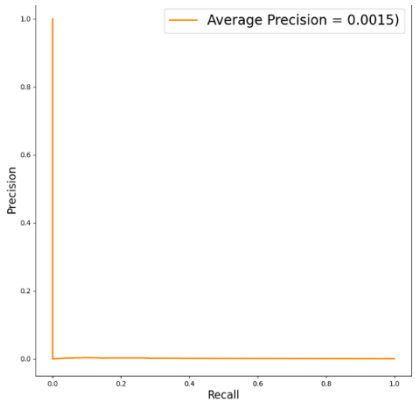

Figure 39 - Switch Precision-Recall Curve

3.5.1.7.3 Model Data

The scope of the model was limited to overhead switches on the distribution system. On average, there were 40 switch failures and 5 ignitions during wildfire season between 2016 – 2022.

Table 14 - Switch Equipment Event Summary

Switch Event Counts				
	Training Data		Testing Data	
Year	Failures	Ignitions	Failures	Ignitions
2016	32	7	14	1
2017	28	4	15	2
2018	21	0	14	0
2019	18	3	13	1
2020	25	3	14	1
2021	37	6	13	0
2022	28	6	9	1
Totals	**189**	**29**	**92**	**6**

3.5.1.7.4 Algorithm Selection

During development Switch failure models were built using SparkML's Random Forest and the Spark version of XGBoost. Ultimately, the XGBoost algorithm was selected for its predictive performance, built-in feature selection, ability to handle missing values, and speedy computation time.

3.5.1.7.5 Covariate Selection

Many switch equipment attributes were tested as features in the model, with the SCADA switch type showing the most performance gains. *Figure 40* presents the total gains feature importance for the Switch equipment model. Among the many equipment attributes experimented with during model development: switch CC rating, soil erodibility, average fire season humidity, and disconnect switch type were found to be the most meaningful features for the model.

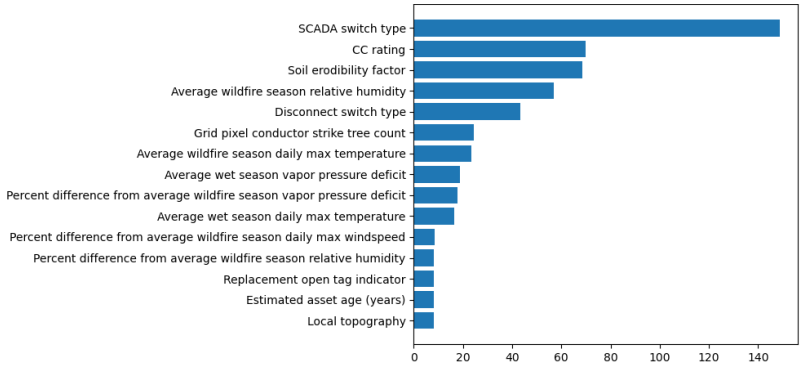

Figure 40 - Switch Feature Importance

Figure 41 shows the SHAP plot for the Switch model. Interpreting the plot, model prediction relationships can be understood and validated. For the Switch equipment, higher probability of failure was found to be correlated with:

- Higher CC rating
- Not disconnect switch
- Is SCADA switch

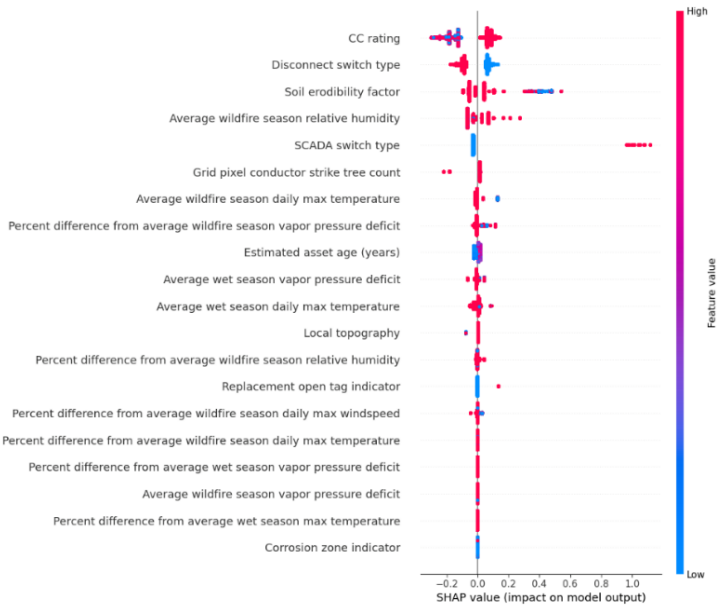

Figure 41 - Switch SHAP Plot

3.5.1.7.6 Limitations and Opportunities

The new v4 switch model demonstrated the capability to use switch attributes with environmental and meteorological features to predict switch equipment failures. Future model development will explore potential improvements such as:

- Using the device switching history of the device - a healthy switch is operated only occasionally and switches that operate frequently tend to degrade.
- Additional research on why SCADA switches are more likely to fail.
- Improving CC rating data set quality.

3.5.1.8 Transformer Models

Transformers are nodes on the distribution grid that are identified by a California Grid Coordinate (cgc12). Each transformer contains from one to three transformer units that are identified by individual equipment IDs. When any unit on a transformer fails, all individual transformer units are typically replaced. Planning programs, therefore, focus on the transformer, whereas failures occur to a transformer unit. The transformer models therefore predict failures for individual transformer units.

The transformer failures are predicted through two causal models for v4:

- Transformer – Equipment failures caused by overload or equipment issues
- Transformer – Leaking failures caused by oil escaping from the transformer unit

3.5.1.8.1 Transformer – Equipment Model

The Transformer – Equipment model predicts physical transformer equipment failures such as winding failures, core failures and loss of neutral. Transformers can potentially fail catastrophically with an explosion that is both a wildfire and a public safety concern. Fortunately, transformers have a very low wildfire ignition to failure rate when compared with other distribution assets.

3.5.1.8.1.1 Key Developments

Key developments for the Transformer – Equipment Failure model include:

- The equipment failure events training data set used for v3, which covered fire season events from 2019 through 2021, was updated to include the 2022 failure events for v4 model development.
- New attributes for v4:
  - Replaced v3 categorized loading values with historical loading data.
  - Open transformer tags
  - Seasonal meteorology
- Equipment failure probabilities and risks are estimated at the asset level for v4 and subsequently aggregated and composited through asset to conductor relationships to produce more accurate v4 circuit segment failure probability and risk values. While structural failures were also modeled at an asset level for v3, the asset level results were converted into spatial pixel values for circuit segment aggregation and compositing. The v3 spatial aggregation frequently resulted in the structural failure probability and risk for any given support structure being shared equally with every conductor asset that occupied the same pixel as the support structure. As a result, the real failure probability and risk values for multiple conductors passing through a single spatial pixel could be higher or lower than the reported aggregated values.

3.5.1.8.1.2 Performance

The v4 Transformer - Equipment failure model demonstrated very good model performance, as shown in *Figure 42* and *Figure 43*, with an AUC of 0.77.

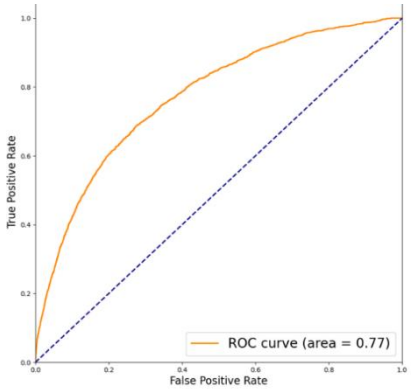

Figure 42 - Transformer - Equipment ROC Curve

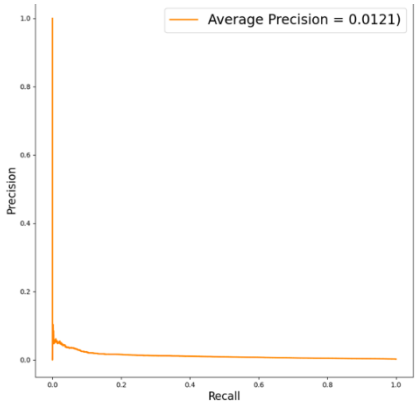

Figure 43 - Transformer - Equipment Precision-Recall Curve

3.5.1.8.1.3 Model Data

The scope of the model was limited to overhead transformer equipment on the distribution system. On average, there were 1,960 transformer equipment failures and 20.5 ignitions during wildfire season between 2019 – 2022.

Table 15 - Transformer - Equipment Event Summary

Transformer - Equipment Event Counts				
	Training Data		Testing Data	
Year	Failures	Ignitions	Failures	Ignitions
2019	1097	18	391	7
2020	1662	18	545	2
2021	1603	15	511	6
2022	1533	14	498	2
Totals	**5895**	**65**	**1945**	**17**

3.5.1.8.1.4 Algorithm Selection

During development Switch failure models were built using SparkML's Random Forest and the Spark version of XGBoost. Ultimately, the XGBoost algorithm was selected for its predictive performance, built-in feature selection, ability to handle missing values, and speedy computation time.

3.5.1.8.1.5 Covariate Selection

Figure 44 presents the total gains top feature importance for the Transformer – Equipment model performance. Top features include peak kVA, transformer age, temperature, resident count, and load factor.

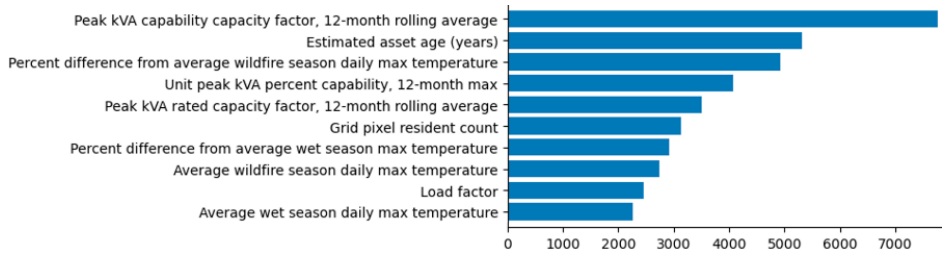

Figure 44 - Transformer - Equipment Top Feature Importance

Other covariate features that moderately contribute to the Equipment failure model include:

- Average wildfire season daily max windspeed
- Soil erodibility factor
- Grid pixel conductor strike tree count
- Local topography
- Rated kVA
- Unit peak kVA percent capability, 12-month rolling average
- Coastal corrosive indicator
- Non-burnable land index
- Manufactured encoded KU
- Manufactured encoded AS
- Manufactured encoded PP
- Manufactured encoded GE
- Manufactured encoded HI
- Manufactured encoded DS
- Manufactured encoded XX
- Replacement open tag indicator
- Manufactured encoded ME
- Manufactured encoded FP
- Manufactured encoded CP
- Manufactured encoded AB
- Manufactured encoded WE

Figure 45 shows the SHAP plot for the Transformer – Equipment failure model. Interpreting the plot, model prediction relationships can be understood and validated. For transformer equipment, higher probability of failure was found to be correlated with:

- Higher peak kVA rated capacity factor
- High percent difference from average max wet season temperature

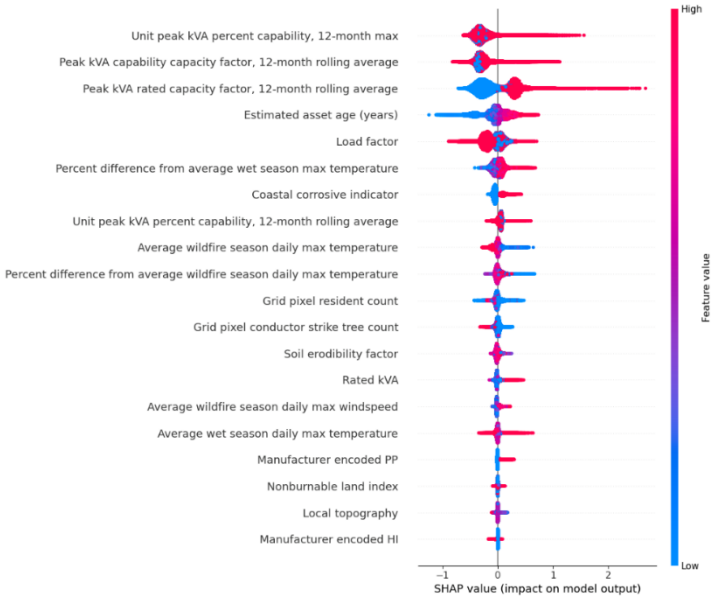

Figure 45 - Transformer - Equipment SHAP Plot

3.5.1.8.1.6 Limitations and Opportunities

Several initiatives could be pursued to improve the transformer equipment failure model performance for future releases by updating the model features, including:

- Additional cleaning of failure and ignition event data to identify specific unit failures
- Explore incorporating additional historical loading data
- Explore incorporating physics-based models for temperature-based adjustments to asset age

3.5.1.8.2 Transformer – Leaking Model

The Transformer – Leaking model predicts tank failures that result in cooling oil leaking out of a transformer. Cooling oil loss leads to overheated equipment and eventual failure of the transformer. While transformer leak failures rarely lead to ignitions, modeling leak failures separately improves the performance of the equipment failure model for predicting equipment-related ignitions.

3.5.1.8.2.1 Key Developments

Key developments for the Transformer – Leaking model include:

- The equipment leaking events training data set used for v3, which covered fire season events from 2019 through 2021, was updated to include the 2022 failure events for v4 model development.
- New attributes for v4:
  - Replaced v3 categorized loading values with historical loading data.
  - Open transformer tags
  - Seasonal meteorology
- Equipment failure probabilities and risks are estimated at the asset level for v4 and subsequently aggregated and composited through asset to conductor relationships to produce more accurate v4 circuit segment failure probability and risk values. While structural failures were also modeled at an asset level for v3, the asset level results were converted into spatial pixel values for circuit segment aggregation and compositing. The v3 spatial aggregation frequently resulted in the structural failure probability and risk for any given support structure being shared equally with every conductor asset that occupied the same pixel as the support structure. As a result, the real failure probability and risk values for multiple conductors passing through a single spatial pixel could be higher or lower than the reported aggregated values.

3.5.1.8.2.2 Performance

The v4 Transformer - Leaking failure model demonstrated very good model performance, as shown in *Figure 46* and, *Figure 47* with an AUC of 0.78.

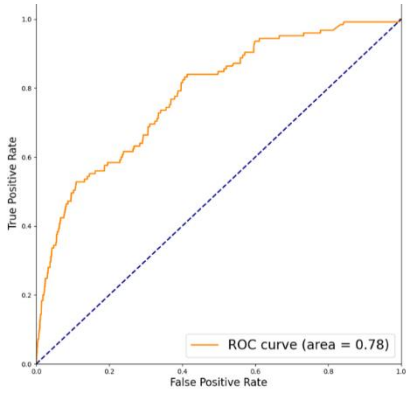

Figure 46 - Transformer - Leaking ROC Curve

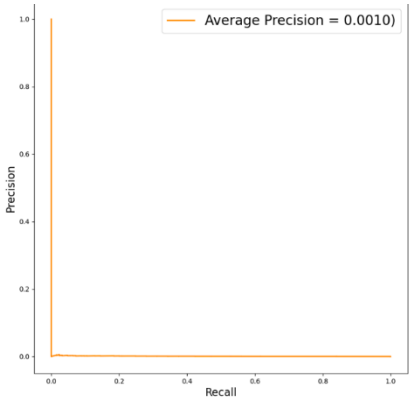

Figure 47 - Transformer - Leaking Precision-Recall Curve

3.5.1.8.2.3 Model Data

The scope of the model was limited to overhead transformer equipment on the distribution system. On average, there were 113 transformer leaking failures and less than one ignition during wildfire season between 2019 – 2022.

Table 16 - Transformer - Leaking Event Summary

Transformer - Leaking Event Counts				
	Training Data		Testing Data	
Year	Failures	Ignitions	Failures	Ignitions
2019	49	0	21	0
2020	88	0	32	0
2021	75	1	22	0
2022	114	0	50	0
Totals	**326**	**1**	**125**	**0**

3.5.1.8.2.4 Algorithm Selection

During development Switch failure models were built using SparkML's Random Forest and the Spark version of XGBoost. Ultimately, the XGBoost algorithm was selected for its predictive performance, built-in feature selection, ability to handle missing values, and speedy computation time.

3.5.1.8.2.5 Covariate Selection

Figure 48 presents the total gains top feature importance for the Transformer – Leaking model performance. Top features include temperature, transformer age, peak KVA, rate kVA resident count, load factor, windspeed, and soil erodibility factor.

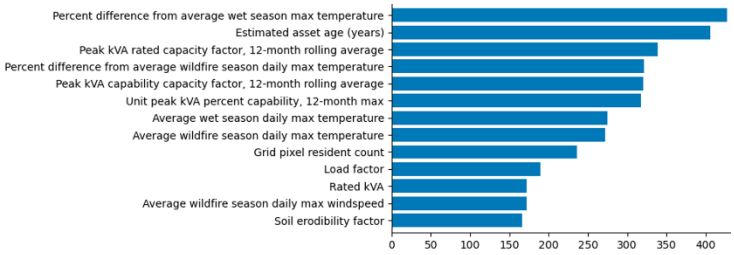

Figure 48 - Transformer - Leaking Top Feature Importance

Other covariate features that moderately contribute to the Leaking failure model include:

- Manufacturer encoded DS
- Local topography
- Grid pixel conductor strike tree count
- Unit peak kVA percent capability, 12-month rolling average
- Manufactured encoded HI
- Manufactured encoded XX
- Manufactured encoded AS
- Manufactured encoded PP
- Non-burnable land index
- Coastal corrosive indicator
- Manufactured encoded GE
- Manufactured encoded KU
- Manufactured encoded ME

Figure 49 shows the SHAP plot for the Transformer – Leaking failure model. Interpreting the plot, model prediction relationships can be understood and validated. For leaking transformers, higher probability of failure was found to be correlated with:

- Higher peak kVA rated capability capacity factor
- Higher peak kVA rated capacity factor
- Unit peak kVA percent capability
- Transformer age

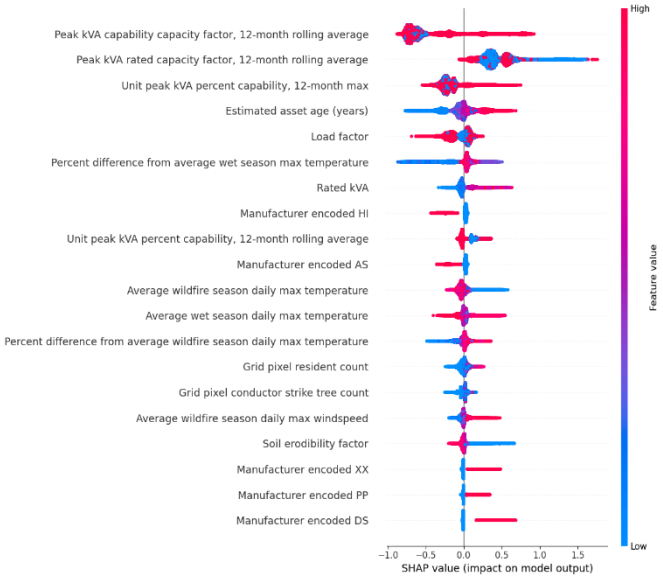

Figure 49 - Transformer - Leaking SHAP Plot

3.5.1.8.2.6 Limitations and Opportunities

Several initiatives could be pursued to improve the transformer equipment failure model performance for future releases by updating the model features, including:

- Additional cleaning of failure and ignition event data to identify specific unit failures
- Explore incorporating additional historical loading data
- Explore incorporating physics-based models for temperature-based adjustments to asset age

3.5.1.9 Voltage Regulator Model

Voltage regulators, also called boosters, help keep the voltage steady on the distribution system. They have a moderate ignition to failure rate compared to other distribution assets.

3.5.1.9.1 Key Developments

Voltage regulator and capacitor bank failure events were bundled together in a common spatial model for v3 using the MaxEnt algorithm. For v4, voltage regulator and capacitor bank failure events are modeled separately. Additionally, the v3 spatial model approach was replaced with a time-series model for v4.

The time-series model upgrade was enabled by establishing voltage regulator asset history back to 2016 through an examination of annual snapshots of Electrical Distribution GIS (EDGIS) asset data. By examining the historical asset data, failures could be traced back to specific equipment in service at the time of failure and the actual attributes of the failed equipment could in turn be used to train the model.

During model development there were some features that were explored, but not included as covariates in the final model:

- Open tags
- Seasonal meteorology data

3.5.1.9.2 Performance

The v4 Voltage Regulator failure model demonstrated moderately good model performance, as shown in *Figure 50* and *Figure 51*, with an AUC of 0.62.

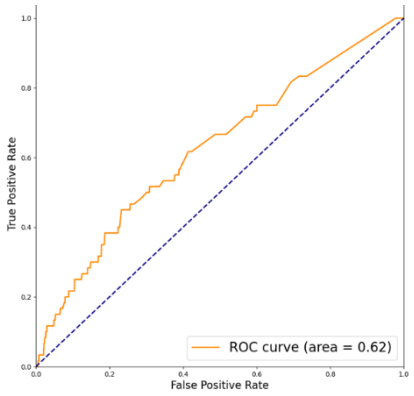

Figure 50 - Voltage Regulator ROC Curve

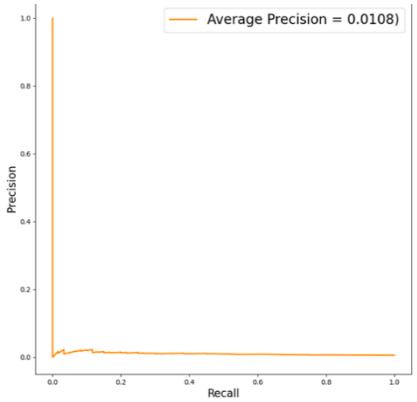

Figure 51 - Voltage Regulator Precision-Recall Curve

3.5.1.9.3 Model Data

The scope of the model was limited to overhead voltage regulators on the distribution system. On average, there were 30.5 voltage regulator failures and 2.7 ignitions during wildfire season between 2016 – 2022.

Table 17 - Voltage Regulator Event Summary

Voltage Regulator Event Counts				
	Training Data		Testing Data	
Year	Failures	Ignitions	Failures	Ignitions
2016	17	1	6	0
2017	19	1	14	2
2018	13	3	7	0
2019	26	1	6	0
2020	21	4	9	1

3.5.1.9.4 Algorithm Selection

During development Voltage Regulator failure models were built using SparkML's Random Forest and the Spark version of XGBoost. Ultimately, the XGBoost algorithm was selected for its predictive performance, built-in feature selection, ability to handle missing values, and speedy computation time.

3.5.1.9.5 Covariate Selection

Many voltage regulator attributes were tested as features in the model with the rate amps showing the most performance gains. *Figure 52* presents the total gains feature importance for the Voltage Regulator model. Among the many equipment attributes experimented with during model development: wet season precipitation, wet season maximum daily temperature, wet season vapor pressure deficit, wildfire season humidity, and percent difference from wildfire season humidity were found to be the most meaningful features for the model.

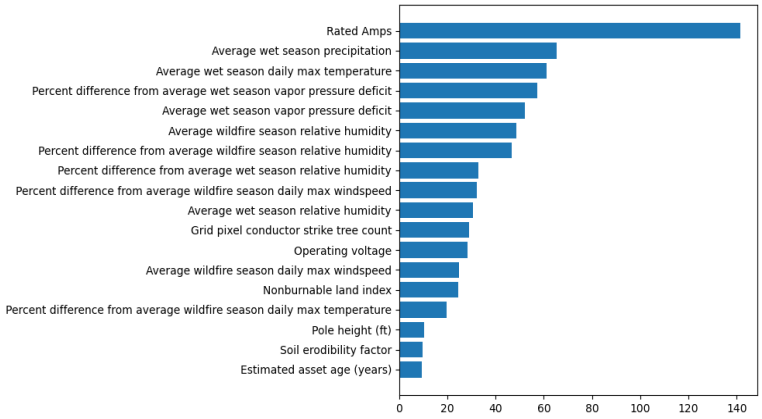

Figure 52 - Voltage Regulator Feature Importance

Figure 53 shows the SHAP plot for the Voltage Regulator model. Interpreting the plot, model prediction relationships can be understood and validated. For Voltage Regulators, higher probability of failure was found to be correlated with:

- Lower wet season precipitation
- Lower fire season humidity
- Higher rated amp values

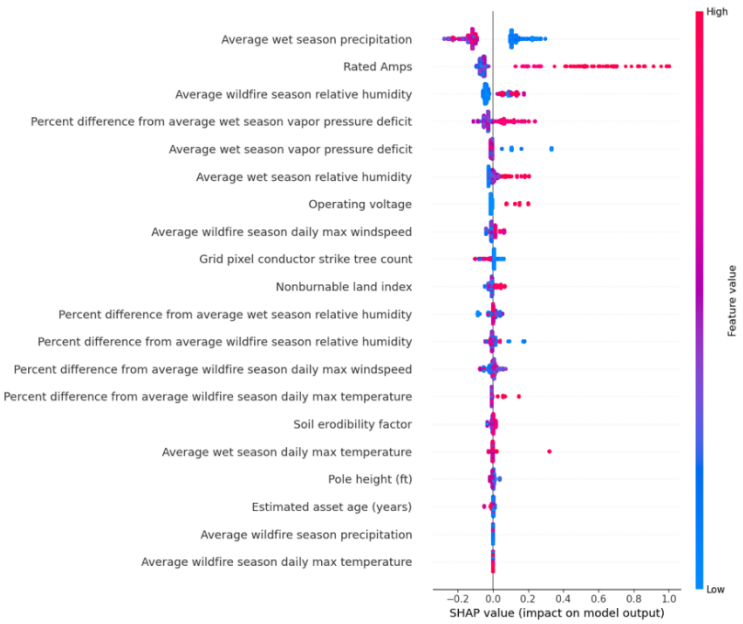

Figure 53 - Voltage Regulator SHAP Plot

3.5.1.9.6 Limitations and Opportunities

The Voltage Regulator model is limited to banks, or groups, of voltage regulators. Unit-specific failure modeling would require additional data not currently available.

Future model development is expected to focus on the exploration of additional voltage regulator attributes and meteorological features.

3.5.1.10 Other Equipment Model

The Other Equipment model is the bookkeeping catch-all for outages with a cause that does not belong with any other causal model or has no recorded cause. Fortunately, while there are a great number of outages that are attributed to the Other Equipment model, there are only a very few outages that result in an ignition. This is likely due to the investigative emphasis placed on ignition records leading to correct attribution of each ignition to its true cause. In the end, the small number of ignitions assigned to the Other Equipment model have a minimal impact on distribution wildfire risk mitigation planning.

3.5.1.10.1 Key Developments

The Other Equipment v4 model is a refresh of the v3 model. The only significant update was the addition of 2023 failures to the event training dataset.

3.5.1.10.2 Performance

The v4 Other Equipment outage model demonstrated good model performance with an AUC of 0.75 as shown in *Figure 54*.

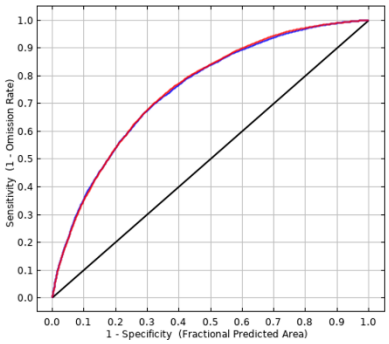

Figure 54 - Other Equipment ROC Curve

3.5.1.10.3 Model Data

Table 18 presents a summary of event counts used for v4 development:

Table 18 – Other Equipment Event Summary

Event Type	Value
Outage Count	54053
Ignition Count	201
Ignitions Per Outage	0.0037

3.5.1.10.4 Algorithm Selection

The MaxEnt algorithm, which was used for v3, was retained for v4 due to its ability to analyze presence only events and preserve spatial interactions during model optimization.

3.5.1.10.5 Covariate Selection

Figure 55 presents the total gains feature importance that account for 95% of the Other Equipment model performance. Top features include strike tree counts, the impervious and non-burnable land indices that indicate urban environments, subtypecd, and conductor size and material.

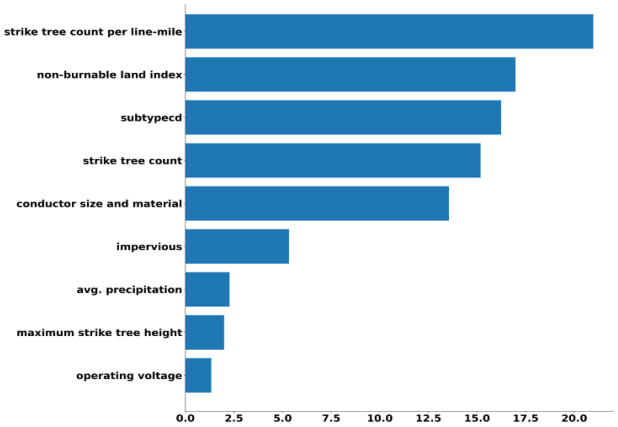

Figure 55 - Other Equipment Top Feature Performance

There are numerous additional covariate features that marginally contribute to the Other Equipment model, accounting for the remaining 5% of model performance:

- avg. strike tree height
- canopy density
- montane hardwood CWHR
- tier-2
- coastal
- soil slope
- P.S.P.S. segment
- montane hardwood CWHR
- soil clay content
- douglas fir CWHR
- soil erodibility factor
- avg. specific humidity
- gusty summer day percentage
- closed cone pine cypress CWHR
- soil drain
- soil horizon thickness
- soil hydro-group
- is soil hydric
- annual soil flood frequency
- windy summer day percentage
- redwood CWHR
- local topography
- soil permeability
- eucalyptus C.W.H.R
- klamath mixed conifer CWHR
- avg. 100-hr fuels
- tree species
- coastal oak woodland CWHR
- valley oak woodland CWHR
- juniper CWHR
- ponderosa pine CWHR
- montane riparian CWHR
- avg. burn index
- avg. daily maximum temperature
- maximum wind speed
- soil organic matter
- sierran mixed conifer CWHR

3.5.1.10.6 Limitations and Opportunities

Deep learning models will be investigated to bring these models into the temporal domain while retaining spatial dependencies.

3.5.2 Contact From Object Models

Contact From Object failures and outages on the distribution grid occur when an electrical short or failure is caused by a non-electrical asset object. Contact From Object failures are grouped into three causal categories:

- Animal - Failures initiated by animal (non-human) contact with an electrical asset.
- Third-Party - Failures initiated by human-related contact with an electrical asset.
- Vegetation - Failures initiated by vegetation in contact with an electrical asset.

Thousands of failures and outages have been recorded for each causal category. To improve model performance and model applicability for developing mitigation response, each of the causal categories have been subdivided to model specific causal failure paths.

The following sections in this document detail the suite of Contact From Object models developed for DEPM v4.

Table 19 provides a brief Contact From Object model performance summary.

Table 19 - Contact From Object Model Performance Summary

Contact From Object Event Model	Outages	v3 p(o)	V4 p(o) – Probability of Outage		
	Season Mean	AUC	AUC	Precision	Concentration Factor
Vegetation – Branch		0.83	0.87	0.000864	3.20
Vegetation – Trunk		0.87	0.88	0.000971	3.40
Vegetation – Other		0.84	0.88	0.000357	2.57
Animal – Bird		0.74	0.75	0.000266	1.79
Animal – Squirrel		0.88	0.88	0.000174	3.70
Animal – Other		0.77	0.80	0.000195	2.53
Third-Party – Balloon		0.89	0.89	0.000305	3.25
Third-Party – Vehicle		0.77	0.76	0.000413	1.85
Third-Party – Other		0.71	0.74	0.000145	1.78

3.5.2.1 Animal Models

Animals frequently come into contact with electrical assets. Animal contact can cause outages and potentially ignitions. Historically, birds and squirrels are responsible for the majority of animal-related outages. Therefore, animal outages are predicted using three distinct models:

- Bird – Failures caused by avian contact with conductors.
- Squirrel – Failures caused by squirrel contact with conductors.
- Other – Failures from other or unknown animal contact.

3.5.2.1.1 Animal – Bird Model

The Animal-Bird model uses historical bird-caused failure events to model outage probability from bird contact with conductors.

3.5.2.1.1.1 Key Developments

There are two important changes to the Bird model for v4:

- The failure event dataset was updated to include 2023 failures, expanding the number of events available for model development.
- New satellite canopy density data from Planet Labs was introduced to improve location correlations for animal habitats.

3.5.2.1.1.2 Performance

The v4 Animal – Bird outage model demonstrated good model performance with an AUC of 0.75, as shown in *Figure 56*.

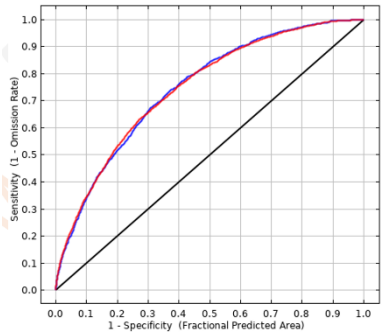

Figure 56 - Animal-Bird ROC Curve

3.5.2.1.1.3 Model Data

Table 20 presents a summary of event counts used for v4 development:

Table 20 - Animal - Bird Event Summary

Event Type	Value
Outage Count	5429
Ignition Count	259
Ignitions Per Outage	0.0477

3.5.2.1.1.4 Algorithm Selection

The MaxEnt algorithm, which was used for v3, was retained for v4 due to its ability to analyze presence only events and preserve spatial interactions during model optimization.

3.5.2.1.1.5 Covariate Selection

Figure 57 presents the total gains feature importance that account for 95% of the Animal - Bird model performance. Top features include conductor type (subtypecd), the number of strike trees, impervious and non-burnable land index that indicate urban environments, and operating voltage.

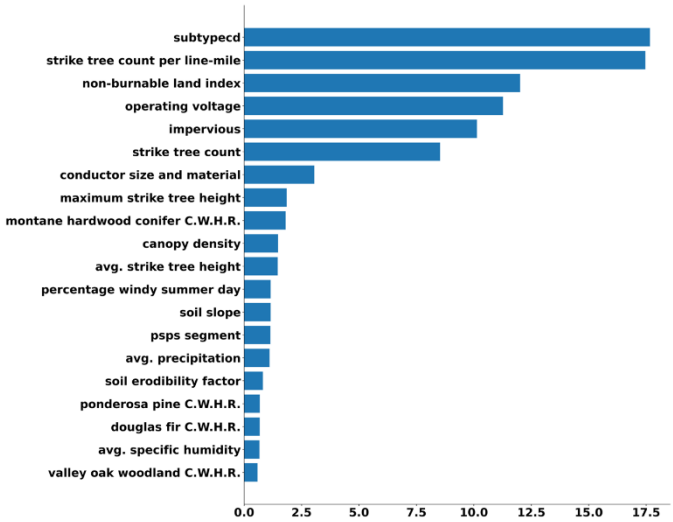

Figure 57 - Animal - Bird Top Feature Importance

There are numerous additional covariate features that marginally contribute to the Bird model, accounting for the remaining 5% of model performance:

- soil organic matter
- closed cone pine cypress CWHR
- tier-2
- tree species
- avg. vapor pressure deficit
- soil hydro-group
- blue oak foothill pine CWHR
- blue oak woodland CWHR
- local topography
- avg. 100-hr fuels
- soil clay content
- avg. 1000-hr fuels
- avg. energy release
- soil liquid limit
- gusty summer day percentage
- avg. wind speed
- minimum strike tree height
- tier-3
- soil permeability
- avg. daily maximum temperature
- soil drain
- soil horizon thickness
- eucalyptus C.W.H.R
- aspen C.W.H.R
- is soil hydric
- juniper CWHR
- available soil water capacity
- maximum wind speed
- montane hardwood CWHR
- annual soil flood frequency
- redwood CWHR

3.5.2.1.1.6 Limitations and Opportunities

Due to the interaction of animals, vegetation, and climate, it is important that the Animal models be able to capture temporal variations over time so that future conditions can be projected based on current trends. The current MaxEnt algorithm, while very good at modeling spatial trends, cannot model temporal trends. Therefore, the model is currently limited to using features such as overall vegetation density and cannot discern time-based trends such as increasing tree mortality and its resultant animal habitat impacts. Deep learning models such as Recurrent Neural Networks and Transformers will be investigated to test if adding the temporal domain to future models will improve model predictive performance.

3.5.2.1.2 Animal – Squirrel Model

The Animal-Squirrel model uses historical squirrel-caused failure events to model outage probability from squirrels interacting with conductors.

3.5.2.1.2.1 Key Developments

There are two important changes to the Squirrel model for v4:

- The failure event dataset was updated to include 2023 failures, expanding the number of events available for model development.
- New satellite canopy density data from Planet Labs was introduced to improve location correlations for animal habitats.

3.5.2.1.2.2 Performance

The v4 Animal – Squirrel outage model demonstrated excellent model performance with an AUC of 0.88, as shown in *Figure 58*.

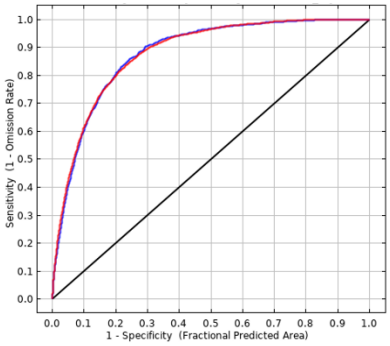

Figure 58 - Animal-Squirrel ROC Curve

3.5.2.1.2.3 Model Data

Table 21 presents a summary of event counts used for v4 development:

Table 21 - Animal-Squirrel Event Summary

Event Type	Value
Outage Count	4488
Ignition Count	51
Ignitions Per Outage	0.0114

3.5.2.1.2.4 Algorithm Selection

The MaxEnt algorithm, which was used for v3, was retained for v4 due to its ability to analyze presence only events and preserve spatial interactions during model optimization.

3.5.2.1.2.5 Covariate Selection

Figure 59 presents the total gains feature importance that account for 95% of the Animal - Squirrel model performance. Top features include impervious and non-burnable land indices that indicate urban environments, average precipitation, strike tree count, and fuel availability.

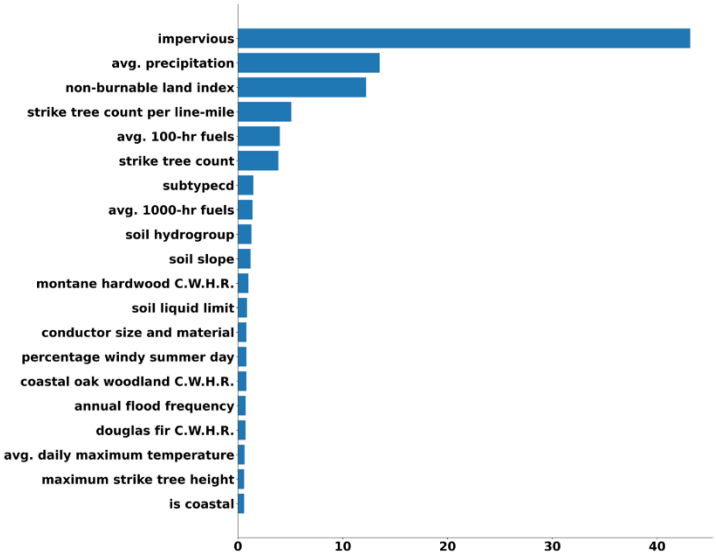

Figure 59 - Animal - Squirrel Top Feature Importance

There are numerous additional covariate features that marginally contribute to the Squirrel model, accounting for the remaining 5% of model performance:

- avg. specific humidity
- soil horizon thickness
- avg. vapor pressure deficit
- valley oak woodland CWHR
- blue oak woodland CWHR
- canopy density
- maximum wind speed
- soil erodibility factor
- eucalyptus C.W.H.R
- avg. strike tree height
- operating voltage
- montane hardwood CWHR
- P.S.P.S. segment
- tier-2
- montane riparian CWHR
- soil clay content
- gusty summer day percentage
- avg. wind speed
- sierran mixed conifer CWHR
- avg. burn index
- tree species
- valley foothill riparian CWHR
- local topography
- eastside pine CWHR
- closed cone pine cypress CWHR
- ponderosa pine CWHR
- soil permeability
- available soil water capacity
- is soil hydric

3.5.2.1.2.6 Limitations and Opportunities

Due to the interaction of animals, vegetation, and climate, it is important that the Animal models be able to capture temporal variations over time so that future conditions can be projected based on current trends. The current MaxEnt algorithm, while very good at modeling spatial trends, cannot model temporal trends. Therefore, the model is currently limited to using features such as overall vegetation density and cannot discern time-based trends such as increasing tree mortality and its resultant animal habitat impacts. Deep learning models such as Recurrent Neural Networks and Transformers will be investigated to test if adding the temporal domain to future models will improve model predictive performance.

3.5.2.1.3 Animal – Other Model

The Animal – Other model uses historical failure events which do not fit within the squirrel or bird category to model outage probability from other animal sources.

3.5.2.1.3.1 Key Developments

There are two important changes to the Animal – Other model for v4:

- The failure event dataset was updated to include 2023 failures, expanding the number of events available for model development.
- New satellite canopy density data from Planet Labs was introduced to improve location correlations for animal habitats.

3.5.2.1.3.2 Performance

The v4 Animal – Other outage model demonstrated very good model performance with an AUC of 0.79, as shown in *Figure 60*.

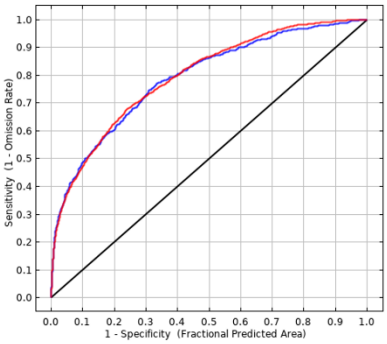

Figure 60 - Animal-Other ROC Curve

3.5.2.1.3.3 Model Data

Table 22 presents a summary of event counts used for v4 development:

Table 22 - Animal - Other Event Summary

Event Type	Value
Outage Count	1291
Ignition Count	105
Ignitions Per Outage	0.0813

3.5.2.1.3.4 Algorithm Selection

The MaxEnt algorithm, which was used for v3, was retained for v4 due to its ability to analyze presence only events and preserve spatial interactions during model optimization.

3.5.2.1.3.5 Covariate Selection

Figure 61 presents the total gains feature importance that account for 95% of the Animal - Squirrel model performance. Top features include impervious and non-burnable land indices that indicate urban environments, strike tree count, vapor pressure deficit and humidity.

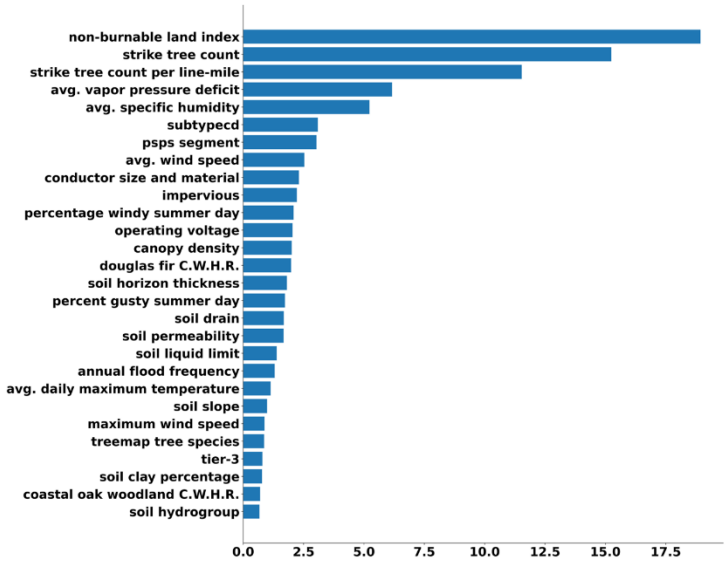

Figure 61 - Animal - Other Top Feature Performance

There are numerous additional covariate features that marginally contribute to the Other model, accounting for the remaining 5% of model performance:

- soil organic matter
- closed cone pine cypress CWHR
- soil erodibility factor
- blue oak woodland CWHR
- avg. burn index
- coastal
- avg. 1000-hr fuels
- available soil water capacity
- avg. strike tree height
- montane hardwood CWHR
- minimum strike tree height
- avg. precipitation
- avg. energy release
- eucalyptus C.W.H.R
- montane riparian CWHR
- valley oak woodland CWHR
- redwood CWHR
- is soil hydric

3.5.2.1.3.6 Limitations and Opportunities

Due to the interaction of animals, vegetation, and climate, it is important that the Animal models be able to capture temporal variations over time so that future conditions can be projected based on current trends. The current MaxEnt algorithm, while very good at modeling spatial trends, cannot model temporal trends. Therefore, the model is currently limited to using features such as overall vegetation density and cannot discern time-based trends such as increasing tree mortality and its resultant animal habitat impacts. Deep learning models such as Recurrent Neural Networks and Transformers will be investigated to test if adding the temporal domain to future models will improve model predictive performance.

3.5.2.2 Third-Party Models

Third-party failures, outages, and ignitions occur when there is human-related contact with electrical assets. Historically, vehicles and mylar balloons are responsible for the majority of human-related outages. Therefore, Third-Party outages are predicted using three distinct models:

- Balloon – Failures caused by mylar balloon contact with conductors.
- Vehicle – Failures caused by a vehicle contact with poles and conductors.
- Other – Failures from other or unknown human-related contact.

3.5.2.2.1 Third-Party – Balloon Model

The Third-Party Balloon model uses historical mylar balloon-caused failure events to model outage probability from balloons contacting conductors.

3.5.2.2.1.1 Key Developments

The only significant change to the Balloon model for v4 was that the failure event data set was updated to include 2023 failures, increasing the number of events used to for modeling training.

3.5.2.2.1.2 Performance

The v4 Third-Party – Balloon outage model demonstrated excellent model performance with an AUC of 0.88, as shown in *Figure 62*.

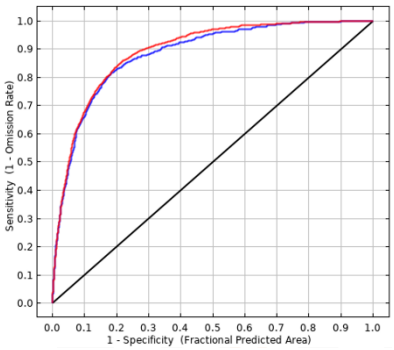

Figure 62 - Third-Party – Balloon ROC Curve

3.5.2.2.1.3 Model Data

Table 23 presents a summary of event counts used for v4 development:

Table 23 - Third-Party – Balloon Event Summary

Event Type	Value
Outage Count	2420
Ignition Count	120
Ignitions Per Outage	0.0496

3.5.2.2.1.4 Algorithm Selection

The MaxEnt algorithm, which was used for v3, was retained for v4 due to its ability to analyze presence only events and preserve spatial interactions during model optimization.

3.5.2.2.1.5 Covariate Selection

Figure 63 presents the total gains feature importance that account for 95% of the Third-Party - Balloon model performance. Top features include the impervious and non-burnable land indices that indicate urban environments, strike tree count, and conductor type (subtypecd).

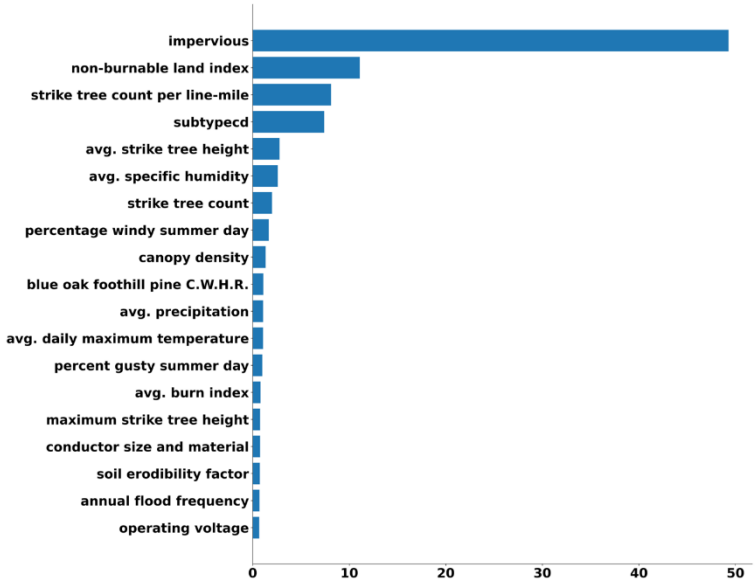

Figure 63 – Third-Party – Balloon Top Feature Importance

There are numerous additional covariate features that marginally contribute to the Balloon model, accounting for the remaining 5% of model performance:

- maximum wind speed
- tier-2
- avg. vapor pressure deficit
- P.S.P.S. segment
- soil horizon thickness
- soil clay content
- closed cone pine cypress CWHR
- sierran mixed conifer CWHR
- red fir CWHR
- soil slope
- soil organic matter
- avg. energy release
- redwood CWHR
- tier-3
- soil drain
- soil hydro-group
- available soil water capacity
- is soil hydric
- minimum strike tree height
- eucalyptus C.W.H.R
- avg. wind speed
- tree species
- soil liquid limit
- valley oak woodland CWHR
- montane riparian CWHR

3.5.2.2.1.6 Limitations and Opportunities

Due to population dynamics, it is important that the Third-Party models be able to capture temporal variations over the years and project into the future based on current trends. The current MaxEnt algorithm, while very good at modeling spatial trends, cannot model temporal trends nor can it see finer trends such as demographic change and (de)urbanization. Deep learning models such as Recurrent Neural Networks and Transformers will be investigated to test if adding the temporal domain to future models will improve model predictive performance.

3.5.2.2.2 Third-Party – Vehicle Model

The Third-Party Vehicle model uses historical vehicle-caused failure events to model outage probability from vehicle contact with electrical assets resulting in damage to conductors.

3.5.2.2.2.1 Key Developments

The only significant change to the Vehicle model for v4 was that the failure event data set was updated to include 2023 failures, increasing the number of events used to for modeling training.

3.5.2.2.2.2 Performance

The v4 Third-Party – Vehicle outage model demonstrated very good model performance with an AUC of 0.76, as shown in *Figure 64*.

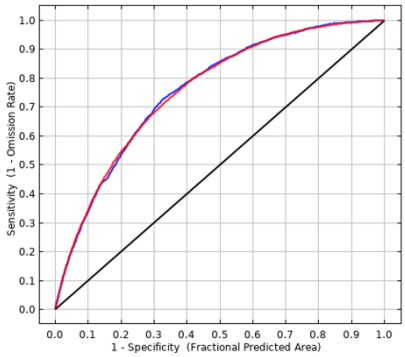

Figure 64 - Third Party-Vehicle ROC Curve

3.5.2.2.2.3 Model Data

Table 24 presents a summary of event counts used for v4 development:

Table 24 – Third-Party – Vehicle Event Summary

Event Type	Value
Outage Count	8347
Ignition Count	305
Ignitions Per Outage	0.0365

3.5.2.2.2.4 Algorithm Selection

The MaxEnt algorithm, which was used for v3, was retained for v4 due to its ability to analyze presence only events and preserve spatial interactions during model optimization.

3.5.2.2.2.5 Covariate Selection

Figure 65 presents the total gains feature importance that account for 95% of the Third-Party - Vehicle model performance. Top features include the impervious and non-burnable land indices that indicate urban environments, strike tree count, conductor type (subtypecd), and conductor size and material.

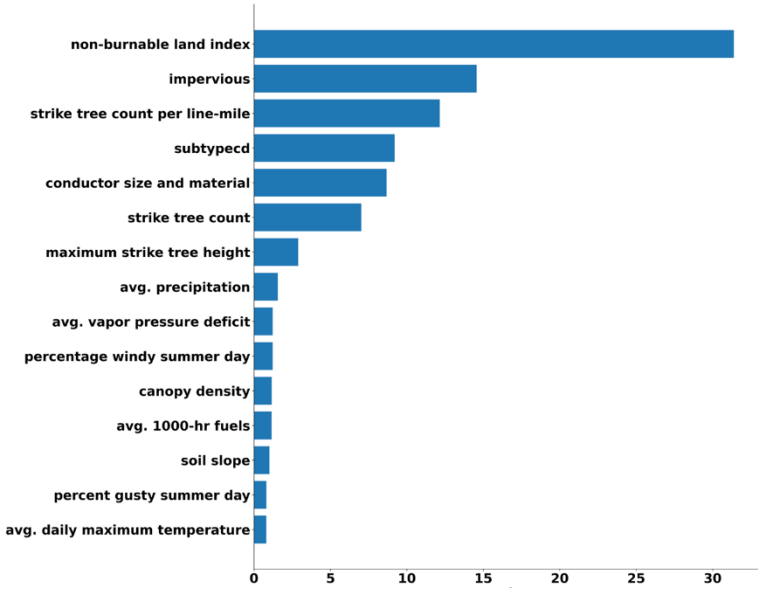

Figure 65 - Third Party-Vehicle Top Feature Performance

There are numerous additional covariate features that marginally contribute to the Vehicle model, accounting for the remaining 5% of model performance:

- soil permeability
- avg. strike tree height
- local topography
- avg. burn index
- operating voltage
- tree species
- soil hydro-group
- P.S.P.S. segment
- ponderosa pine CWHR
- coastal oak woodland CWHR
- soil liquid limit
- available soil water capacity
- montane hardwood CWHR
- tier-3
- is soil hydric
- blue oak foothill pine CWHR
- soil drain
- juniper CWHR
- avg. wind speed
- blue oak woodland CWHR
- soil erodibility factor
- sierran mixed conifer CWHR
- eucalyptus C.W.H.R
- avg. 100-hr fuels
- montane hardwood CWHR
- closed cone pine cypress CWHR
- annual soil flood frequency
- tier-2
- soil horizon thickness
- valley oak woodland CWHR
- soil clay content
- redwood CWHR

3.5.2.2.2.6 Limitations and Opportunities

Due to population dynamics, it is important that the Third-Party models be able to capture temporal variations over the years and project into the future based on current trends. The current MaxEnt algorithm, while very good at modeling spatial trends, cannot model temporal trends nor can it see finer trends such as demographic change and (de)urbanization. Deep learning models such as Recurrent Neural Networks and Transformers will be investigated to test if adding the temporal domain to future models will improve model predictive performance.

3.5.2.2.3 Third-Party – Other Model

The Third-Party – Other model uses historical third-party failure events that are not classified as mylar balloon or vehicle-related failures.

3.5.2.2.3.1 Key Developments

The only significant change to the Third-Party – Other model for v4 was that the failure event data set was updated to include 2023 failures, increasing the number of events used to for modeling training.

3.5.2.2.3.2 Performance

The v4 Third-Party – Other outage model demonstrated good model performance with an AUC of 0.74, as shown in *Figure 66*.

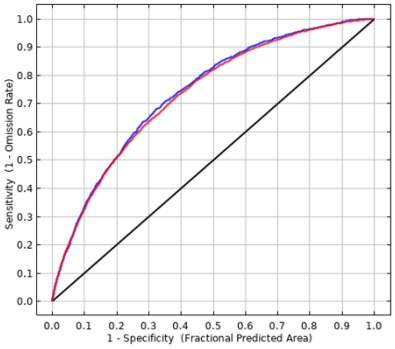

Figure 66 - Third Party-Other ROC Curve

3.5.2.2.3.3 Model Data

Table 25 presents a summary of event counts used for v4 development:

Table 25 - Third-Party – Other Event Summary

Event Type	Value
Outage Count	2785
Ignition Count	151
Ignitions Per Outage	0.0542

3.5.2.2.3.4 Algorithm Selection

The MaxEnt algorithm, which was used for v3, was retained for v4 due to its ability to analyze presence only events and preserve spatial interactions during model optimization.

3.5.2.2.3.5 Covariate Selection

Figure 67 presents the total gains feature importance that account for 95% of the Third-Party - Other model performance. Top features include the impervious and non-burnable land indices that indicate urban environments, strike tree count, conductor type (subtypecd), and strike tree height.

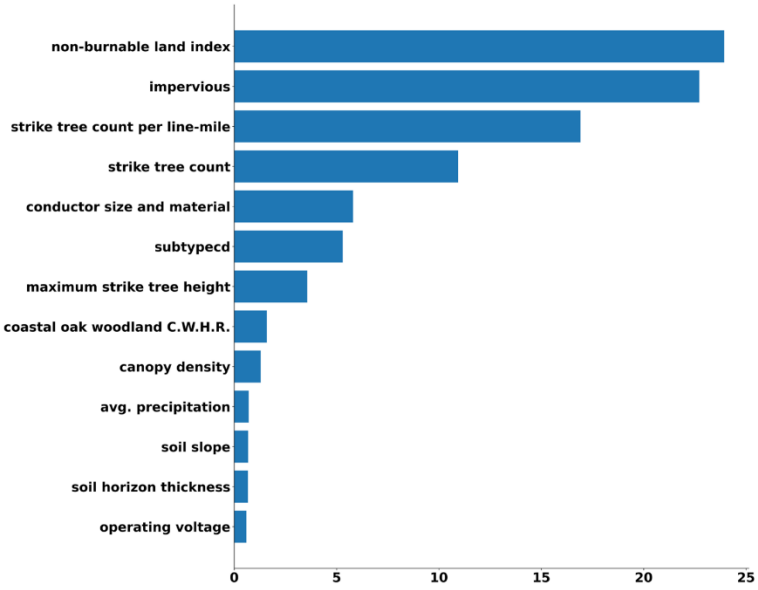

Figure 67 - Third Party-Other Top Feature Performance

There are numerous additional covariate features that marginally contribute to the Other model, accounting for the remaining 5% of model performance:

- avg. specific humidity
- avg. strike tree height
- windy summer day percentage
- avg. vapor pressure deficit
- annual soil flood frequency
- tier-3
- tier-2
- avg. daily maximum temperature
- soil liquid limit
- Klamath mixed conifer CWHR

- available soil water capacity
- juniper CWHR
- avg. wind speed
- eucalyptus C.W.H.R
- desert riparian CWHR
- ponderosa pine CWHR
- avg. energy release
- maximum wind speed

3.5.2.2.3.6 Limitations and Opportunities

Due to population dynamics, it is important that the Third-Party models be able to capture temporal variations over the years and project into the future based on current trends. The current MaxEnt algorithm, while very good at modeling spatial trends, cannot model temporal trends nor can it see finer trends such as demographic change and (de)urbanization. Deep learning models such as Recurrent Neural Networks and Transformers will be investigated to test if adding the temporal domain to future models will improve model predictive performance.

3.5.2.3 Vegetation Models

Vegetation regularly comes into contact with electrical assets and often initiates failure, outages, and ignitions. Historically, trees, through two causal paths, are responsible for majority of vegetation-related failures and outages. Therefore, vegetation outages are predicted using three distinct models:

- Branch – Failures caused by tree branches striking conductors.
- Trunk – Failures caused by full tree body striking conductors.
- Other – Failures from other or unknown vegetation causes.

3.5.2.3.1 Vegetation – Branch Model

The Vegetation – Branch model uses historical branch failure events to model outage probability from branch debris striking a conductor.

3.5.2.3.1.1 Key Developments

During v4 development, we explored the issue of bark beetle infestation as a source of tree failures. A study was conducted to discern the cause of the infestations and it was found that the lack of water availability over the years, primarily due to Climate Change, was hampering the tree's immune system and natural defenses. These effects were captured by way of the following remotely sensed quantities and the surveyed tree mortality map by CalFIRE:

- The Standardized Precipitation and Evapo-Transpiration Index – An index used to quantify regional water availability.
- The Climatic Water Deficit – This quantity represents the water use of trees in the area.
- California High Hazard Zones – This CalFIRE product was used to give the model a sense of the tree mortality rate in any given area.

Other important model developments for v4 include:

- Planet Labs Tree Canopy Density – Similar to counting the number of strike trees around an asset, a measure of the canopy density was used to quantify the amount of material that was available to be ejected from any given tree.
- Wind Strike Potential – New attributes were introduced to consider the relative position of trees to conductors along with wind speed and direction to when predicting branch strike potential.
- Tree Failure Locations – Tree failures were attributed to actual tree locations for v4, whereas v3 used the locations of triggered protective devices.

3.5.2.3.1.2 Performance

The v3 Branch model lagged the Trunk model in performance. The addition of the new covariates improved the v4 Branch model and it now matches the Trunk Model in performance. The v4 Vegetation – Branch outage model demonstrated excellent model performance with an AUC of 0.87, as shown in *Figure 68*.

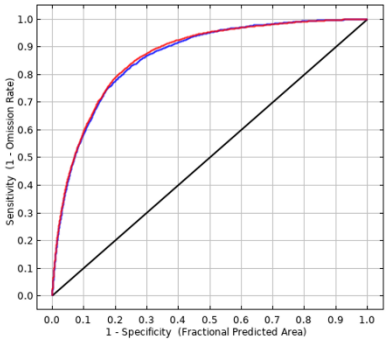

Figure 68 - Vegetation-Branch ROC Curve

3.5.2.3.1.3 Model Data

Table 26 presents a summary of event counts used for v4 development:

Table 26 – Vegetation - Branch Event Summary

Event Type	Value
Outage Count	7392
Ignition Count	428
Ignitions Per Outage	0.058

In addition to updated target events, newly added covariates were also generated by various base data:

- The Standardized Precipitation and Evapo-transpiration Index (SPEI) represents water availability. This index measures the deviation of drought conditions from a multi-year baseline quantifying the onset, duration, and magnitude of drought.
- The Climatic Water Deficit (CWD) measures vegetation water use. The CWD data comes from the USGS Water Basin Characterization Model.
- As a proxy for tree mortality, both tier-1 and tier-2 CalFIRE California High Hazard Zones were implemented as covariates.
- Canopy Density was implemented from a dataset from Planet Labs.
- The following new wind covariates were developed:
  - The normalized historical wind direction and strike potential
  - The historical wind direction and strike potential
  - The wind damage and strike potential
  - The normalized wind damage and strike potential which measure different ways in which a wind's magnitude and direction interplay with a tree's location and a conductor's location to ultimately propel matter into a conductor.

3.5.2.3.1.4 Algorithm Selection

The MaxEnt algorithm, which was used for v3, was retained for v4. A significant issue for the vegetation models is inability to determine a target probability of a vegetation failure causing damage to an electrical asset. Unfortunately, a vegetation failure is only recorded as failure if it impacts an electrical asset. Therefore, no information is available about how many benign vegetation failures occur that do not result in an asset problem. The MaxEnt algorithm is particularly suited for modeling vegetation failures as it only requires knowledge of known asset failure locations caused by falling branches or tree trunks and does not require data on failures that did not result in an asset impact.

3.5.2.3.1.5 Covariate Selection

Figure 69 presents the total gains feature importance that account for 95% of the Vegetation - Branch model performance. Top features include strike tree counts, strike tree height, the impervious and non-burnable land indices that indicate urban environments, and conductor (subtypecd).

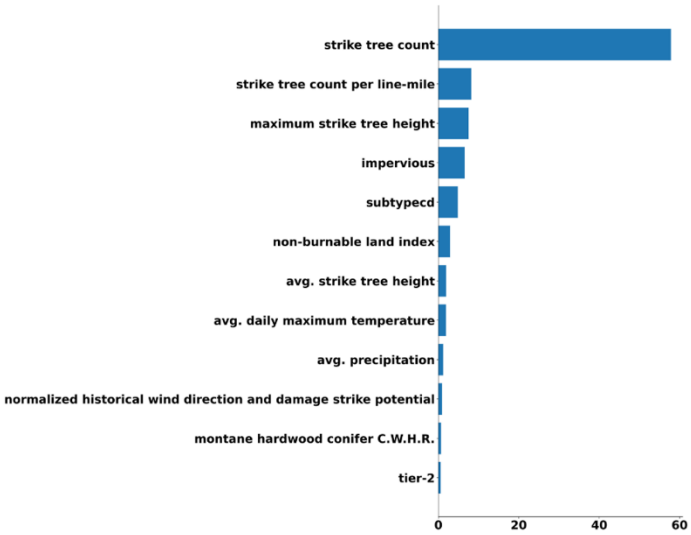

Figure 69 - Vegetation-Branch Top Feature Performance

There are numerous additional covariate features that marginally contribute to the Branch model, accounting for the remaining 5% of model performance:

- blue oak foothill pine CWHR
- operating voltage
- wind damage and strike potential
- coastal
- soil hydro-group
- maximum 4-yr CWD
- valley foothill riparian CWHR
- douglas fir CWHR
- soil permeability
- avg. specific humidity
- soil slope
- gusty summer day percentage
- historical wind direction strike pot ential
- annual soil flood frequency
- soil drain
- coastal oak woodland CWHR
- canopy density
- avg. 20-yr S.P.E.I.
- normalized historical wind directi on strike potential
- local topography
- is soil hydric
- windy summer day percentage
- closed cone pine cypress CWHR
- coefficient of variation 4-yr CWD
- avg. energy release
- avg. wind speed
- avg. 100-hr fuels
- tree species
- avg. vapor pressure deficit
- soil liquid limit
- tier-2 tree mortality H.H.Z.
- soil horizon thickness
- soil clay content
- lodgepole pine CWHR
- soil erodibility factor
- blue oak woodland CWHR
- eucalyptus C.W.H.R
- maximum 20-yr CWD

3.5.2.3.1.6 Limitations and Opportunities

There are two significant opportunities to strengthen the vegetation models for future releases.

The first opportunity is to extend our modeling into the temporal domain. As vegetation grows and changes over the years, it is important to capture this change along with its interplay with a changing climate. Deep learning architectures such as Recurrent Neural Networks and Transformers will be

explored in the future to include this temporal dimension. In addition, the use of Planet Labs data products will be used to model tree conditions from 2016 onward to accurately reflect the changing vegetation conditions from growth, failure, and mitigation efforts by vegetation management.

The second area where improvement can be made is that tree mortality is not accurately captured by the CalFIRE dataset. Yearly tree mortality data has been purchased from Planet Labs, and is being prepared for use in future models. It is expected that the new tree mortality data will be included for the next version of the vegetation models.

3.5.2.3.2 Vegetation – Trunk Model

The Vegetation – Trunk model uses historical tree body, or trunk, failure events to model outage probability from tree falls striking a conductor.

3.5.2.3.2.1 Key Developments

During v4 development, we explored the issue of bark beetle infestation as a source of tree failures. A study was conducted to discern the cause of the infestations and it was found that the lack of water availability over the years, primarily due to Climate Change, was hampering the tree's immune system and natural defenses. These effects were captured by way of the following remotely sensed quantities and the surveyed tree mortality map by CalFIRE:

- The Standardized Precipitation and Evapo-Transpiration Index – An index used to quantify regional water availability.
- The Climatic Water Deficit – This quantity represents the water use of trees in the area.
- California High Hazard Zones – This CalFIRE product was used to give the model a sense of the tree mortality rate in any given area.

Other important model developments for v4 include:

- Planet Labs Tree Canopy Density – Similar to counting the number of strike trees around an asset, a measure of the canopy density was used to quantify the amount of material that was available to be ejected from any given tree.
- Wind Strike Potential – New attributes were introduced to consider the relative position of trees to conductors along with wind speed and direction to when predicting branch strike potential.
- Tree Failure Locations – Tree failures were attributed to actual tree locations for v4, whereas v3 used the locations of triggered protective devices.

3.5.2.3.2.2 Performance

The v4 Vegetation – Trunk outage model demonstrated excellent model performance with an AUC of 0.88, as shown in *Figure 70*.

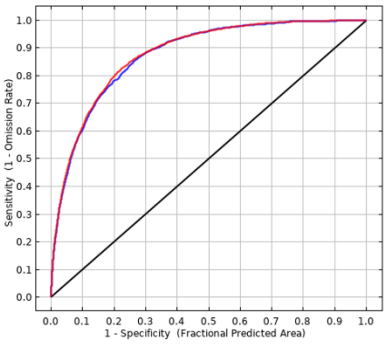

Figure 70 - Vegetation-Trunk ROC Curve

3.5.2.3.2.3 Model Data

Table 27 presents a summary of event counts used for v4 development:

Table 27 - Vegetation - Trunk Event Summary

Event Type	Value
Outage Count	4630
Ignition Count	344
Ignitions Per Outage	0.074

In addition to updated target events, newly added covariates were also generated by various base data:

- The Standardized Precipitation and Evapo-transpiration Index (SPEI) represents water availability. This index measures the deviation of drought conditions from a multi-year baseline quantifying the onset, duration, and magnitude of drought.
- The Climatic Water Deficit (CWD) measures vegetation water use. The CWD data comes from the USGS Water Basin Characterization Model.
- As a proxy for tree mortality, both tier-1 and tier-2 CalFIRE California High Hazard Zones were implemented as covariates.
- Canopy Density was implemented from a dataset from Planet Labs.
- The following new wind covariates were developed:
  - The normalized historical wind direction and strike potential
  - The historical wind direction and strike potential
  - The wind damage and strike potential
  - The normalized wind damage and strike potential which measure different ways in which a wind's magnitude and direction interplay with a tree's location and a conductor's location to ultimately propel matter into a conductor.

3.5.2.3.2.4 Algorithm Selection

The MaxEnt algorithm, which was used for v3, was retained for v4. A significant issue for the vegetation models is inability to determine a target probability of a vegetation failure causing damage to an electrical asset. Unfortunately, a vegetation failure is only recorded as failure if it impacts an electrical asset. Therefore, no information is available about how many benign vegetation failures occur that do not result in an asset problem. The MaxEnt algorithm is particularly suited for modeling vegetation failures as it only requires knowledge of known asset failure locations caused by falling branches or tree trunks and does not require data on failures that did not result in an asset impact.

3.5.2.3.2.5 Covariate Selection

Figure 71 presents the total gains feature importance that account for 95% of the Vegetation - Trunk model performance. Top features include strike tree counts, strike tree height, and subtypecd.

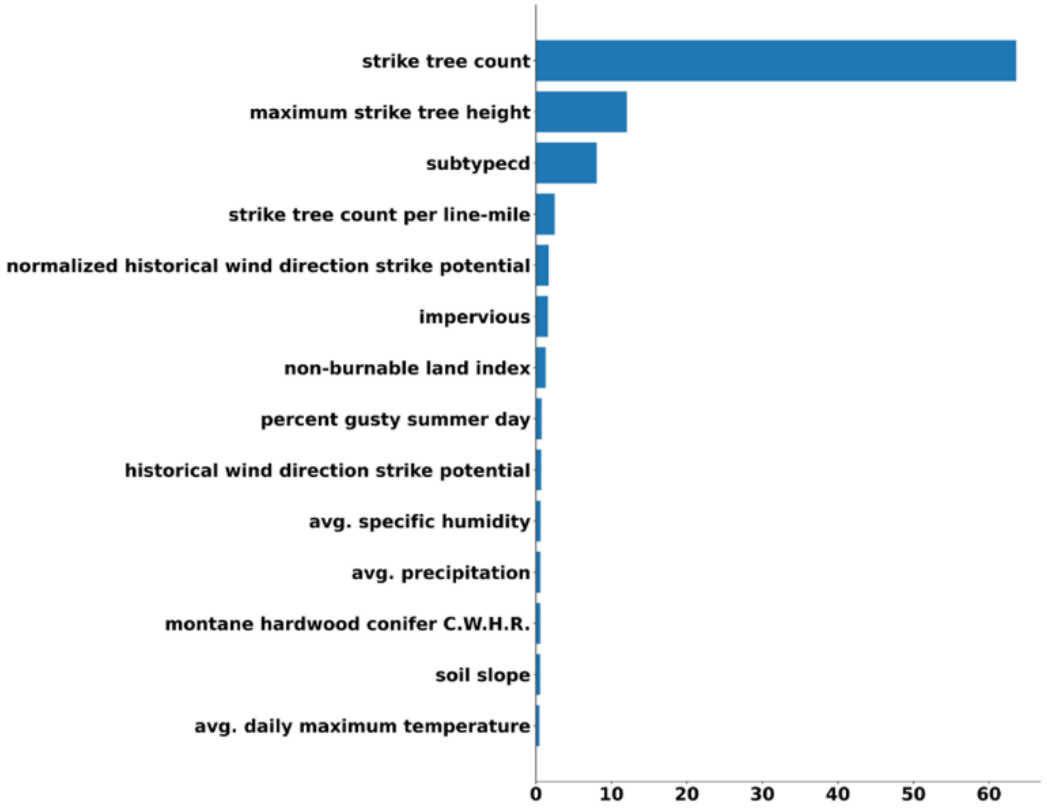

Figure 71 - Vegetation-Trunk Top Feature Performance

There are numerous additional covariate features that marginally contribute to the Trunk model, accounting for the remaining 5% of model performance:

- avg. 1000-hr fuels
- avg. vapor pressure deficit
- soil hydro-group
- eucalyptus CWHR
- maximum 20-yr CWD
- canopy density
- soil clay content
- avg. wind speed
- normalized wind damage and str ike potential
- soil permeability
- tier-2 tree mortality H.H.Z.
- blue oak foothill pine CWHR
- juniper CWHR
- wind damage / strike potential
- avg. 20-yr S.P.E.I.
- coefficient of variation 4-yr CWD
- coefficient of variation 20-yr CW D
- tree species
- soil horizon thickness
- avg. burn index
- local topography
- white fir CWHR
- operating voltage
- closed cone pine cypress CWHR
- valley foothill riparian CWHR
- windy summer day percentage
- coastal oak woodland CWHR
- montane riparian CWHR
- avg. strike tree height
- avg. energy release
- soil erodibility factor
- sierran mixed conifer CWHR
- red fir CWHR
- soil drain
- maximum 4-yr CWD
- pinyon juniper CWHR
- is soil hydric
- tier-3
- ponderosa pine CWHR
- sub-alpine conifer CWHR
- coastal
- maximum 20-yr S.P.E.I.
- douglas fir CWHR

3.5.2.3.2.6 Limitations and Opportunities

There are two significant opportunities to strengthen the vegetation models for future releases.

The first opportunity is to extend our modeling into the temporal domain. As vegetation grows and changes over the years, it is important to capture this change along with its interplay with a changing climate. Deep learning architectures such as Recurrent Neural Networks and Transformers will be explored in the future to include this temporal dimension. In addition, the use of Planet Labs data products will be used to model tree conditions from 2016 onward to accurately reflect the changing vegetation conditions from growth, failure, and mitigation efforts by vegetation management.

The second area where improvement can be made is that tree mortality is not accurately captured by the CalFIRE dataset. Yearly tree mortality data has been purchased from Planet Labs, and is being prepared for use in future models. It is expected that the new tree mortality data will be included for the next version of the vegetation models.

3.5.2.3.3 Vegetation – Other Model

The Vegetation – Other model uses historical failure events related to third-party, snow load, wind, and unclassified events to model outage probability.

3.5.2.3.3.1 Key Developments

During v4 development, we explored the issue of bark beetle infestation as a source of tree failures. A study was conducted to discern the cause of the infestations and it was found that the lack of water availability over the years, primarily due to Climate Change, was hampering the tree's immune system and natural defenses. These effects were captured by way of the following remotely sensed quantities and the surveyed tree mortality map by CalFIRE:

- The Standardized Precipitation and Evapo-Transpiration Index – An index used to quantify regional water availability.
- The Climatic Water Deficit – This quantity represents the water use of trees in the area.
- California High Hazard Zones – This CalFIRE product was used to give the model a sense of the tree mortality rate in any given area.

Other important model developments for v4 include:

- Planet Labs Tree Canopy Density – Similar to counting the number of strike trees around an asset, a measure of the canopy density was used to quantify the amount of material that was available to be ejected from any given tree.
- Wind Strike Potential – New attributes were introduced to consider the relative position of trees to conductors along with wind speed and direction to when predicting branch strike potential.
- Tree Failure Locations – Tree failures were attributed to actual tree locations for v4, whereas v3 used the locations of triggered protective devices.

3.5.2.3.3.2 Performance

The v4 Vegetation – Other outage model demonstrated excellent model performance with an AUC of 0.88, as shown in *Figure 72*.

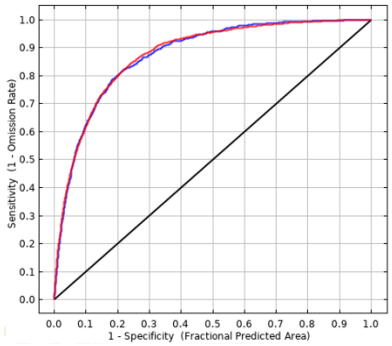

Figure 72 - Vegetation-Other ROC Curve

3.5.2.3.3.3 Model Data

Table 28 presents a summary of event counts used for v4 development:

Table 28 - Vegetation - Other Event Summary

Event Type	Value
Outage Count	1931
Ignition Count	233
Ignitions Per Outage	0.115

3.5.2.3.3.4 Algorithm Selection

The MaxEnt algorithm, which was used for v3, was retained for v4. A significant issue for the vegetation models is inability to determine a target probability of a vegetation failure causing damage to an electrical asset. Unfortunately, a vegetation failure is only recorded as failure if it impacts an electrical asset. Therefore, no information is available about how many benign vegetation failures occur that do not result in an asset problem. The MaxEnt algorithm is particularly suited for modeling vegetation failures as it only requires knowledge of known asset failure locations caused by falling branches or tree trunks and does not require data on failures that did not result in an asset impact.

3.5.2.3.3.5 Covariate Selection

Figure 73 presents the total gains feature importance that account for 95% of the Vegetation - Other model performance. Top features include strike tree counts, the impervious and non-burnable land indices that indicate urban environments, subtypecd, and strike tree height.

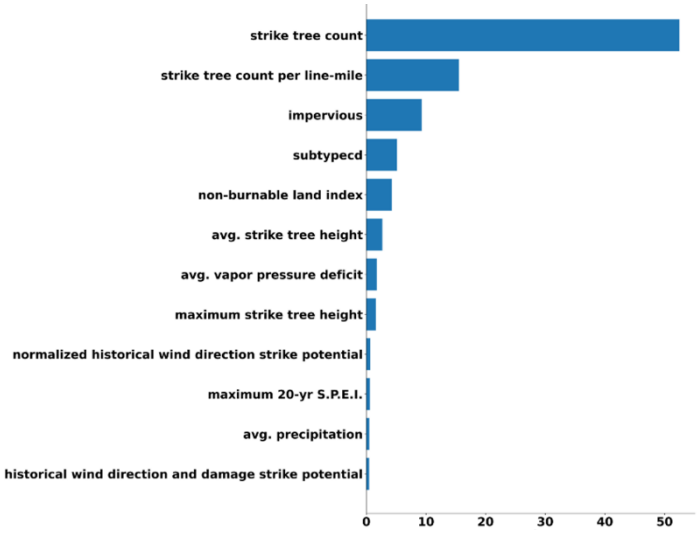

Figure 73 - Vegetation-Other Top Feature Performance

There are numerous additional covariate features that marginally contribute to the Other model, accounting for the remaining 5% of model performance:

- tier-2 tree mortality H.H.Z.
- avg. burn index
- operating voltage
- Coefficient of variation 20-yr S.P.E.I.
- coastal oak woodland CWHR
- blue oak woodland CWHR
- available soil water capacity
- soil hydro-group
- avg. 20-yr S.P.E.I.
- soil erodibility factor
- tier-3
- avg. energy release
- maximum wind speed
- soil permeability
- canopy density
- closed cone pine cypress CWHR
- historical wind direction strike potential
- windy summer day percentage
- tree species
- soil slope
- soil organic matter
- ponderosa pine CWHR
- avg. specific humidity
- annual soil flood frequency
- avg. 1000-hr fuels
- soil liquid limit
- gusty summer day percentage
- valley foothill riparian CWHR
- klamath mixed conifer CWHR
- local topography
- montane riparian CWHR
- normalized wind damage and strike potential
- soil clay content
- juniper CWHR
- jeffrey pine CWHR
- montane hardwood CWHR
- minimum 20-yr S.P.E.I.
- redwood CWHR
- avg. wind speed

3.5.2.3.3.6 Limitations and Opportunities

There are two significant opportunities to strengthen the vegetation models for future releases.

The first opportunity is to extend our modeling into the temporal domain. As vegetation grows and changes over the years, it is important to capture this change along with its interplay with a changing climate. Deep learning architectures such as Recurrent Neural Networks and Transformers will be

explored in the future to include this temporal dimension. In addition, the use of Planet Labs data products will be used to model tree conditions from 2016 onward to accurately reflect the changing vegetation conditions from growth, failure, and mitigation efforts by vegetation management.

The second area where improvement can be made is that tree mortality is not accurately captured by the CalFIRE dataset. Yearly tree mortality data has been purchased from Planet Labs and is being prepared for use in future models. It is expected that the new tree mortality data will be included for the next version of the vegetation models.

3.6 Probability of Ignition Model

The probability of ignition p(i) is the likelihood that an asset-based ignition will occur during a fire season. Probability of ignition is predicted by the Probability of Ignition Given Outage model using the probability of outage predictions from all of the Asset Equipment and Contact From Object models along with other attributes such as environmental conditions. Fire season probability of ignitions are individually predicted for each specific Asset Equipment and Contact From Object model.

3.6.1 Probability of Ignition Given Outage

The Probability of Ignition Given Outage model, p(i|o), takes as its input the results from an Asset Equipment or Contact From Object model, p(o). The percentage of outages that result in an ignition varies, as one would expect, on the outage type. The p(i|o) model uses failure model-specific attributes and environmental conditions to determine the likelihood that a given outage is likely to result in an ignition.

For asset-based event models, the probability of ignition for a given asset is the product of its probability of ignition given an outage and its probability of an outage:

$$p(i)_{asset} = p(i|o)_{asset} * p(o)_{asset}$$

For Contact From Object models, which are location, pixel-based models, the probability of ignition for a given location is the product of the location probability of ignition given outage and the location probability of outage for a specific model:

$$p(i)_{loc} = p(i|o)_{loc} * p(o)_{loc}$$

Individual asset and contact from object probabilities can be composited to determine a summed probability of ignition for a location:

$$p(i)_{loc} = \sum_{loc/asset} p(i|o)_{loc/asset} * p(o)_{loc/asset}$$

Where:

asset	Modeled asset type: conductor, transformer, support structure, etc.
loc	Asset location expressed as a 100m square pixel within the PG&E service territory
p(i)	Probability of Ignition
p(i|o)	Probability of Ignition given an Outage
p(o)	Probability of Outage

3.6.1.1 Key Developments

The p(i|o) model developed for the DEPM v4 provides two substantial improvements over the v3 model:

- Event cause and equipment type interaction terms
- EPSS compensation

The p(i|o) model correlates to failure/outage rates, weather conditions, fuel conditions and availability, and other location-specific attributes. However, the correlation between fuel and weather conditions and ignition outcomes also depends on the nature of the underlying events. Specifically, some events, like transformer failures predominantly result in pole fires that are not influenced by fuels on the ground, while others, like insulator tracking faults, require moisture and condensation for an event to occur. The introduction of event cause and equipment type labels for events allowed the use of interaction terms that

produce separate weather and fuels correlation terms for distinct groups of events that share the same characteristics.

An important purpose for the p(i|o) model is to support tradeoffs between mitigation strategies, including EPSS. Therefore, the v4 p(i|o) model needed to be calibrated to predict the number of ignitions that would be expected without EPSS. Section *3.3* explains how the ignitions event training data was modified to account for EPSS impacts.

3.6.1.2 Performance

Table 29 provide an overview of the p(i|o) performance for the entire suite of probability of failure/outage models. The important outcome to understand from this table is whether the p(i|o) model improves the ability to predict ignitions against the assumption that you can directly predict an ignition from the prediction of a failure/outage. The Delta AUC column highlights the p(i|o) improvement for predicting ignitions, where a positive number is an improvement, a negative number is a degradation. Note that the two models that show the most degradation using the p(i|o) model are also low performing probability of failure/outage models.

Table 29 – p(i|o) Predictive Performance Gain

Event Model	p(o) AUC	p(i) AUC	Delta AUC	p(o) Conc. Factor	p(i) Conc. Factor
Animal – Bird	0.651	0.683	**0.032**	1.79	2.16
Animal – Squirrel	0.839	0.852	0.013	3.70	3.91
Animal - Other	0.741	0.756	0.015	2.53	2.93
Capacitor Bank	0.558	0.549	-0.009	1.40	1.40
DPD	0.625	0.475	-0.151	1.00	1.50
Fuse	0.669	0.681	0.013	2.00	2.10
Primary Conductor – Line Slap	0.770	0.757	-0.013	3.33	3.33
Primary Conductor – Wire Down	0.628	0.639	0.010	1.91	1.78
Primary Conductor - Other	0.694	0.706	0.013	2.75	2.50
Secondary Conductor	0.718	0.728	0.010	2.49	2.59
Support Structure - Electrical	0.854	0.848	-0.006	3.90	3.70
Support Structure - Equipment	0.602	0.654	**0.052**	1.63	2.02
Switch	0.637	0.608	-0.029	1.67	1.67
Third-Party - Balloon	0.801	0.817	0.016	3.25	3.42
Third-Party - Vehicle	0.681	0.712	**0.031**	1.85	2.23
Third-Party - Other	0.613	0.672	**0.060**	1.78	2.05
Transformer – Equipment	0.725	0.748	0.023	2.94	3.53
Transformer – Leaking	0.865	0.845	-0.019	5.00	5.00
Vegetation - Branch	0.804	0.824	0.020	3.20	3.43
Vegetation - Trunk	0.825	0.832	0.007	3.40	3.45
Vegetation - Other	0.760	0.771	0.010	2.57	2.74
Voltage Regulator	0.739	0.720	-0.019	2.00	2.00
Other Equipment	0.640	0.650	0.010	1.82	2.05

The p(i|o) model was fit using a random selection of 75% of the target set data, with the remaining 25% set aside for predictive performance testing. The model classification performance is illustrated in *Figure 74* showing the training and testing ROC curves. The ROC curve indicates the degree to which model assigns elevated ignition probabilities to outages that were associated with real ignitions. The curve demonstrates that the p(i|o) model performs very well, capturing 80% of true ignitions after covering just under 25% of the target set in rank order.

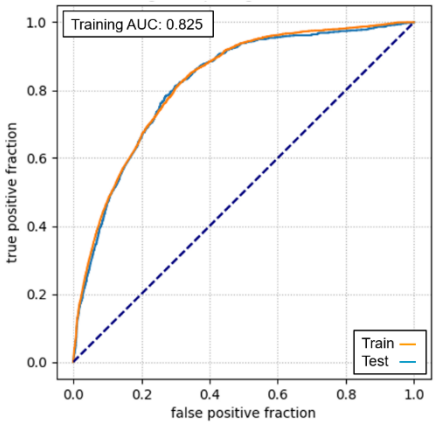

Figure 74 - p(i|o) ROC Curve

3.6.1.3 Model Data

The various outage types predicted by the Asset Equipment and Contact From Object event models have different physical pathways to ignition and, therefore, different rates of ignitions as shown in *Table 30*. A few examples of different ignition routes include:

- Conductor and tree trunk failures often lead to wire down events, placing fault current directly in contact with ground fuels.
- Conductor line slap and branch contacts may cause phase faults, with arcing or combustion that can lead to molten metal, sparks, or flaming branches falling onto ground fuels.
- Equipment tracking, with current arcing across damp, dirty equipment, can often lead to pole fires, which in many cases fail to ignite ground fuels at all.

Table 30 – Outage and Ignition Event Counts Summary

Event Model	Outages (count)	Ignitions (count)	Ignitions per Outage
Animal – Bird	5,429	259	4.77%
Animal – Squirrel	4,488	51	1.14%
Animal - Other	1,291	105	8.13%
Capacitor Bank	370	125	**33.78%**
DPD	624	70	11.22%
Fuse	4,474	245	5.48%
Primary Conductor – Line Slap	938	39	4.16%
Primary Conductor – Wire Down	5,317	553	10.40%
Primary Conductor - Other	1,961	191	9.74%
Secondary Conductor	3,318	223	6.72%
Support Structure - Electrical	4,033	**835**	20.70%
Support Structure - Equipment	4,314	212	4.91%
Switch	790	59	7.47%
Third-Party - Balloon	2,420	120	4.96%
Third-Party - Vehicle	8,347	305	3.65%
Third-Party - Other	2,785	151	5.42%
Transformer – Equipment	14,297	292	2.04%
Transformer – Leaking	753	**1**	**0.13%**
Vegetation - Branch	7,392	428	5.79%
Vegetation - Trunk	4,630	344	7.43%
Vegetation - Other	1,931	223	11.55%
Voltage Regulator	**286**	29	10.14%
Other Equipment	**54,053**	201	0.37%
All Event Models	**134,241**	**5,061**	**3.77%**

3.6.1.4 Algorithm Selection

The v4 p(i|o) model, like the v3 version, is a Logistic Regression model. Random Forest models were also examined but were found to produce similar predictive power but with worse interpretability. Logistic Regression is well-suited for isolating the impact of weather and fuel conditions on ignition rates and supports a semi-causal interpretation of model results.

The introduction of event cause and equipment type interaction terms for v4 required the implementation of a more sophisticated feature generation and selection approach, not just for model training, but also for predicting at all locations across all representative days to produce marginalized expected annual ignition

3.6.1.5 Covariate Selection

The multiple paths to ignition events are influenced differently by environmental conditions such as fuel moisture and wind. Therefore, the p(i|o) model must reflect that the outages predicted by each outage event model have their own unique interaction with environmental variables.

Unfortunately, from a modeling perspective, many of the event models do not have enough historical ignitions that can be used for p(i|o) model training. The lack of sufficient training data makes it likely that a model would be over-fit and subsequently perform poorly against test data. To compensate, outage event models with similar ignition behaviors in response to environmental conditions were grouped together to improve p(i|o) model performance. Optimal performance was achieved using the model groups defined in *Table 31*.

Table 31 - p(i|o) Modeling Groups

Model Group	Member Models	Outages (count)	Ignitions (count)	Ignitions per Outage
1	Vegetation – Branch, Vegetation – Trunk	12,022	751	6.2%
2	Support Structure – Electrical	4,033	713	17.7%
3	Animal – Squirrel, Third-Party – Balloon, Third-Party – Vehicle, Third-Party – Other	18,040	613	3.4%
4	Primary Conductor – Wire Down	5,317	515	9.7%
5	DPD, Capacitor Bank, Fuse, Switch, Voltage Regulator	6,544	498	7.6%
6	Animal – Bird, Animal – Other, Primary Conductor – Line Slap, Transformer – Leaking	8,411	388	4.6%
7	Transformer – Equipment	14,297	269	1.9%
8	Secondary Conductor	3,318	220	6.6%
9	Vegetation – Other	1,931	209	10.8%
10	Other Equipment	54,053	188	0.3%
11	Support Structure – Equipment	4,314	187	4.3%
12	Primary Conductor – Other	1,961	179	9.1%

Many combinations of model-grouped and ungrouped attributes were tested as features in the p(i|o) model. *Figure 75* presents the total gains feature importance for the highest performing features in the p(i|o) model.

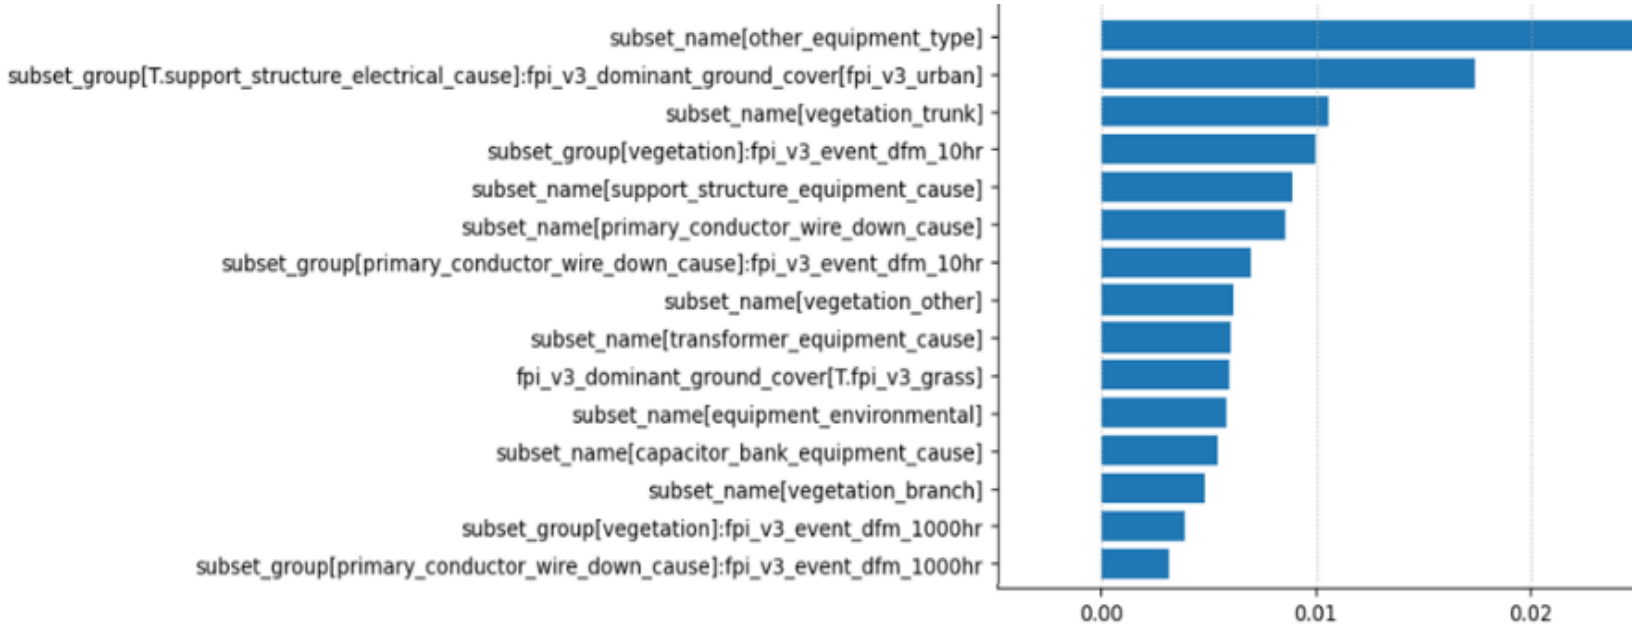

Figure 75 - p(i|o) Top Feature Importance

Other covariate features that moderately contribute to the p(i|o) model include:

- subset_group [vegetation other]: fpi v3 event dfm 10hr
- subset_group [T.support structure equipment]: fpi v3 dominant ground cover [fpi v3 urban]
- subset_group [T.vegetation]: fpi v3 dominant ground cover [fpi v3 grass shrub]
- subset_name [animal squirrel]
- subset_group [other2]: fpi v3 event dfm 1000hr
- fpi_dominant_ground_cover[T.fpi v3 shrub]
- subset_group [support structure electrical]: fpi v3 event dfm 1000hr
- subset_group [other2]: fpi v3 event dfm 10hr
- subset_group [T.other2]: fpi v3 dominant ground cover [fpi v3 grass shrub
- subset_name [transformer leaking]
- subset_group [T.vegetation other]: fpi v3 dominant ground cover [fpi v3 grass shrub]
- subset_group [T.other equipment]: fpi v3 dominant ground cover [fpi v3 grass]
- subset_group [T.protection actuation]: fpi v3 dominant ground cover [fpi v3 grass]
- subset_group [support structure equipment]: fpi v3 event dfm 10hr

- subset_group [T.support structure electrical]: fpi v3 dominant ground cover [fpi v3 timber litter]
- subset_group [T.transformer equipment]: fpi v3 dominant ground cover [fpi v3 timber litter]
- subset_group [secondary conductor]: fpi v3 event dfm 10hr
- subset_group [other equipment]: fpi v3 event dfm 10hr
- subset_group [primary conductor other]: fpi v3 event dfm 1000hr
- subset_group [sother1]: fpi v3 event dfm 10hr
- subset_group [T.transformer equipment]: fpi v3 dominant ground cover [fpi v3 grass]]
- subset_group [T.primary conductor other]: fpi v3 dominant ground cover [fpi v3 grass shrub]
- subset_name [DPD]
- subset_group [T.primary conductor wire down]: fpi v3 dominant ground cover [fpi v3 grass shrub]
- subset_group [other1]: fpi v3 event dfm 1000hr
- subset_group [T.secondary conductor]: fpi v3 dominant ground cover [fpi v3 grass]
- subset_group [vegetation other]: fpi v3 event dfm 1000hr
- subset_group [T.support structure equipment]: fpi v3 dominant ground cover [fpi v3 shrub]
- subset_group [T.transformer equipment]: fpi v3 dominant ground cover [fpi v3 shrub]
- subset_group [transformer equipment]: fpi v3 event dfm 1000hr
- subset_group [transformer equipment]: fpi v3 event dfm 10hr
- subset_group [T.primary conductor other]: fpi v3 dominant ground cover [fpi v3 timber understory]

- subset_group [T.vegetation other]: fpi v3 dominant ground cover [fpi v3 shrub]
- subset_group [support structure electrical]: fpi v3 event dfm 10hr

3.6.1.6 Limitations and Opportunities

One of the defining features of the p(i|o) model is the relative scarcity of ignition data and the diversity of underlying causes and characteristics of related grid failure and outage events. This limits the approaches available to predict ignition rates and requires the introduction of model structure and other assumptions based on first principles. Future work can continue to refine the event groupings that provide shared response to weather and fuel conditions. Model structures capable of predicting well based upon limited training data should continue to be tested as possible alternative algorithms.

The ideal p(i|o) model would have perfect information about fault current, duration, and path to ground as well as finer resolution in time and space of fuel conditions, soil moisture, etc. While this data that is not currently sensed and available, knowledge about their potential influence can factor into model structure and assumptions as well as guide future data gathering initiatives.

4 Future Plans

Several future developments are planned for the distribution event probability models. *Figure 76* provides an overview of RaDA team development plans with Distribution Event Probability Model plans in highlighted in blue font.

Products	2026 WMP	Future WMP

Event Probability Models	• Data Quality Improvement
	• Model Refresh / Calibration
	• Asset Models – Distribution
	  • Switches
	  • Fuses
	  • Capacitor Banks
	  • Voltage Regulators
	• Asset Health – Tags
	• Work Plan Model Causality
	• Animal/Third Party – Distribution
	• Vegetation
	  • Tree Mortality
	  • Time Series Update
	• Insulator Contamination Update
		• Data Quality Improvements
		• Model Refresh / Calibration
		• Full Year Models
		• Asset Model – Distribution
		  • Secondary Conductor
		• Underground Assets
		• Lightning
		• Seismic – Distribution
		• Third Party – Transmission

Risk Models	• WDRM v4 • WTRM v2 • Public Safety Risk Model v2 • Reliability Risk Model v1 • Integrated Grid Planning	• WDRM Update • WTRM Update • Risk Mitigation Automation • Risk Reduction Reporting
Consequence Models	• Wildfire Consequence v4 • Wildfire Egress Impact • Wildfire Suppression Impact • Public Safety Consequence v2 • Reliability Consequence v1	• Wildfire Consequence Update • Conflagration • Vulnerable Communities • WUI Population Growth

Figure 76 - RaDA Product Plan – Distribution Event Probability Models

General development plans for all event probability of failure/outage models include:

- Develop suite of probability of outage given failure models to support reliability risk modeling.
- Improved situational awareness of model performance during wildfire season.
- Enhanced tooling to identify and explain changes between model releases.
- Enhanced tooling for automation and ML operations.

The Equipment Asset models will be expanded by developing:

- New Underground equipment models for:
  - Conductors
  - Switches
  - Transformers
- Secondary Conductor model will be transitioned from a spatial pixel model into an asset model.
- Improved equipment failure reporting in the Asset Failure Data Collection.

The Contact From Object models will be improved through:

- Migration to temporal use of multi-year satellite imagery.
- Potential use of inspections and tags as features, especially for the Vegetation models.
- Failure location data quality enhancements.

The Equipment Asset models will also undergo specific development for integration with Integrated Grid Planning (IGP):

- Enhance probability of failure models to predict for both wildfire season and full calendar year.
- Create a methodology to expand predictions from 1-year to 10-year failure probabilities.

Future Probability of Ignition model development will explore:

- Incorporation of new and improved FPI model predictions from Meteorology.
- Improvements to the model data pipeline, including a more flexible feature regularization approach.
- Additional data informing estimates of the effectiveness of the EPSS program.
- Exploratory work on imputing and incorporating fault characteristics into the model.

WP016A – EPSS Toy Problem

EPSS Outage Risk Calculation Flow - Circuit Segment Level

Analysis for Example Circuit Segment: OAKLAND K 1103CR188 (Low Risk Category)

Overview

This guide shows how data flows from raw WDRM model outputs to final circuit segment EPSS outage risk through 6 datasets.

Attachment: The supplemental Excel file, *EPSS Toy Problem Calculations (Attach. B, WP016B)*, supports this Workpaper (*Attach. B,* WP016A) by providing example data that traces how raw WDRM model outputs flow through six datasets to calculate final circuit segment EPSS outage risk. The file includes examples for three circuit segments representing high, medium, and low risk levels, classified along two dimensions: the expected number of EPSS-attributable outages per wildfire season and the typical customer-minutes of interruption per such event. Please reference the Index sheet in the supplemental Excel file to identify the corresponding sheets for each risk-level example.

Note, this workpaper walks through the low-risk example for OAKLAND K 1103CR188, while the supporting excel file contains the corresponding inputs and outputs for all three risk-level examples.

Core Equation:

EPSS Outage Risk ($) = Σ (prob_epss_failure_s × dollarized_consequence_epss_enabled_s)
− Σ (prob_non_epss_failure_s × dollarized_consequence_epss_disabled_s)

for all subsets s (23 failure mode subsets across conductors and structures)

where: dollarized_consequence = customers_impacted x outage_duration x customer_value_of_service

Calculation Flow:

Dataset 1: Raw WDRM Probability of Failure (PoF) (wdrm_cs_pof)
↓ (multiply by enablement rate)
Dataset 2: EPSS Enablement (epss_enablement)
↓ (multiply by sustained outage fraction)
Dataset 3: Sustained Outage Fraction (sustained_outage_fraction)
↓ (datasets 1, 2, and 3 combine to produce dataset 4)
Dataset 4: EPSS PoF (cs_epss_pof)

↓ (combine with consequence)
Dataset 5: Consequence (cs_consequence)
↓ (PoF × Consequence = Risk)
Dataset 6: Final EPSS Outage Risk (cs_epss_outage_risk)

The 23 Failure Mode Subsets:

#	Subset Name	Asset Type
1	primary_conductor_line_slap_cause	Conductor
2	primary_conductor_wire_down_cause	Conductor
3	primary_conductor_other_cause	Conductor
4	third_party_balloon	Conductor
5	third_party_other	Conductor
6	vegetation_branch	Conductor
7	vegetation_trunk	Conductor
8	vegetation_other	Conductor
9	other_equipment_type	Conductor
10	secondary_conductor	Conductor
11	capacitor_bank_equipment_cause	Structure
12	dpd_equipment_cause	Structure
13	fuse_equipment_cause	Structure
14	support_structure_equipment_cause	Structure
15	support_structure_electrical_cause	Structure
16	switch_equipment_cause	Structure
17	transformer_equipment_cause	Structure
18	transformer_equipment_leaking	Structure
19	voltage_regulator_equipment_cause	Structure
20	animal_bird	Structure
21	animal_squirrel	Structure
22	animal_other	Structure
23	third_party_vehicle	Structure

Note: switch_equipment_cause, transformer_equipment_cause, and transformer_equipment_leaking are zeroed out. Their PoF is set to 0 because these failure modes are considered independent of EPSS.

Dataset 1: Raw WDRM PoF (wdrm_cs_pof)

What is this?

The WDRM v4 (Wildfire Risk Distribution Model version 4) predicts outage frequency during wildfire season (June–November) for each failure mode subset, aggregated to the circuit segment level.

One row = One circuit segment's wildfire-season failure rates across all 23 subsets.

These values represent the expected number of outages of this type on this circuit segment during a single wildfire season.

Where does it come from?

The WDRM v4 model is a source dataset to help build the EPSS model. The raw model predictions are consumed as an input and filtered to only circuit segments in HFTD (High Fire Threat District) or HFRA (High Fire Risk Area).

Key Columns

Column	Description
cs_name	Circuit segment identifier
circuit_name	Circuit name (multiple circuit segments to a circuit)
subset_name	Expected outage count during wildfire season for that failure mode

Example: OAKLAND K 1103CR188 (sample of subsets)

Subset	WDRM Failure Rate (outages/WF season)
vegetation_branch	0.2505
primary_conductor_wire_down_cause	0.1270
other_equipment_type	0.4051
animal_bird	0.0285
support_structure_equipment_cause	0.0604
transformer_equipment_cause	0.2068

Dataset 2: EPSS Enablement (epss_enablement)

What is this?

The historical fraction of wildfire season days that EPSS was enabled on the circuit containing our circuit segment. This is a circuit-level value (not circuit-segment-level) because EPSS is enabled/disabled at the circuit level.

Where does it come from?

Calculated from two historical periods:

- **2017–2020:** Retrospective estimates of EPSS enablement based on current criteria
- **2022–present:** historical count of days EPSS was enabled during fire season

Note, 2021 was a pilot year for EPSS and was excluded from the analysis

epss_enablement = total_days_epss_enabled / total_days_wf_season

(Each wildfire season = 183 days, June 1 – November 30)

Example: OAKLAND K 1103

Column	Value
circuit_name	OAKLAND K 1103
total_days_epss_enabled	139
total_days_wf_season	1,281
epss_enablement (days epss is enabled/ total wf season days)	**0.1085**

Dataset 3: Sustained Outage Fraction (sustained_outage_fraction)

What is this?

The system-wide fraction of outages that are sustained (as opposed to momentary) for each failure mode subset. This is not circuit-segment specific, it applies globally to all circuit segments.

Why does this matter?

When EPSS is enabled, all outages become sustained. When EPSS is NOT enabled, only ~83% of outages are naturally sustained. This fraction lets us calculate the counterfactual: "Of the outages during EPSS-enabled times, how many would have been sustained anyway?"

Where does it come from?

Derived from historical outage data:

- Filtered to: wildfire season (June–Nov), pre-2022 (EPSS deployed in 2022), non-EPSS events, HFTD/HFRA circuits
- sustained_outage_fraction = sustained_outage_count / outage_count

Example Rows (sample):

subset_name	outage_count	sustained_outage_count	sustained_fraction (sustained outages / total outages)
vegetation_branch	5,693	5,585	0.9810
primary_conductor_wire_down_cause	2,836	2,697	0.9510
other_equipment_type	33,470	22,310	0.6666
animal_bird	4,498	4,318	0.9600

Dataset 4: EPSS PoF (cs_epss_pof)

What is this?

The computed probability of failure values for our circuit segment under two scenarios:

- **prob_epss_failure_s** - Expected outage frequency for subset s during EPSS-enabled periods
- **prob_non_epss_failure_s** - Counterfactual outage frequency during those same periods, as if EPSS were not enabled

Calculations

For each subset:

- prob_epss_failure_s = WDRM_failure_rate_s (Dataset 1) × epss_enablement (Dataset 2)
- prob_non_epss_failure_s = prob_epss_failure_s × sustained_outage_fraction_s (Dataset 3)

Example: vegetation_branch

prob_epss_failure = 0.2505 × 0.1085 = 0.027176
prob_non_epss_failure = 0.027176 × 0.9810 = 0.026661

Example: animal_bird

prob_epss_failure = 0.0285 × 0.1085 = 0.003095
prob_non_epss_failure = 0.003095 × 0.9600 = 0.002971

Dataset 5: Consequence (cs_consequence)

What is this?

The expected impact of an outage on this circuit segment, how long it lasts and how many customers are affected. Values are averages across all assets (structures or conductors) on the circuit segment.

Key Concept

Consequence differs between EPSS-enabled and EPSS-disabled scenarios because more customers are impacted under EPSS since EPSS devices de-energize a wider section of the circuit than traditional protective devices.

Consequence is calculated separately for conductors and structures because they have different outage durations and different upstream EPSS devices.

Data Descriptions

Input Component	Description
expected_outage_duration	average outage duration in minutes, derived from 5 calendar years of historical outage data (2019–2024), filtered to sustained, non-major-event, distribution equipment failures, grouped by asset type and protective device type
mean_customers_impacted_by_EPSS	average number of customers who would lose power if an EPSS device trips, averaged across all conductors and structures on the circuit segment (each asset is mapped to its nearest upstream EPSS device's downstream customer count).
mean_customers_impacted_by_non_EPSS	average number of customers who would experience a sustained outage from an equipment failure, averaged across all conductors and structures on the circuit segment
avg_customer_value_of_service	Average cost per customer-minute of interruption, averaged across all EPSS devices serving this circuit segment. Derived from classifying each downstream customer as Residential ($0.08/customer-minute) or Non-Residential ($23.11/customer-minute) and averaging
Output Component	**Description**
CMI consequence	Customer-minutes interrupted per outage when EPSS is enabled/not-enabled
Dollarized consequence	Cost per outage when EPSS is enabled/not-enabled

Calculations

CMI and dollarized consequence are calculated separately for conductor and structure asset types.

cmi_consequence_epss_enabled_[asset type] =
mean_customers_impacted_by_EPSS_[asset type] × expected_outage_duration_[asset type]

cmi_consequence_epss_disabled_[asset type] =
mean_customers_impacted_by_non_EPSS_[asset type] ×
expected_outage_duration_[asset type]

dollarized_consequence_epss_enabled_[asset type] =
cmi_consequence_epss_enabled_[asset type] × avg_customer_value_of_service_[asset type]

dollarized_consequence_epss_disabled_[asset type] =
cmi_consequence_epss_disabled_[asset type] ×
avg_customer_value_of_service_[asset type]

Example: OAKLAND K 1103CR188

Column	Conductors	Structures
expected_duration (minutes)	250.55	259.72
mean_customers_impacted_by_EPSS	668	683.15
mean_customers_impacted_by_non_EPSS	241.96	193.13
avg_customer_value_of_service ($/min)	$1.2177	$1.2151

CMI (customers * duration)

cmi_consequence_epss_enabled_conductors = 668 × 250.55 = 167,367.81
cmi_consequence_epss_disabled_conductors = 241.96 × 250.55 = 60,623.61
cmi_consequence_epss_enabled_structures = 683.15 × 259.72 = 177,429.81
cmi_consequence_epss_disabled_structures = 193.13 × 259.72 = 50,160.73

Dollarized Consequence (CMI * value of service)

dollarized_consequence_epss_enabled_conductors = 167,367.81 × $1.2177 = $203,805.39
dollarized_consequence_epss_disabled_conductors = 60,623.61 × $1.2177 = $73,821.95
dollarized_consequence_epss_enabled_structures = 177,429.81 × $1.2151 = $215,592.45
dollarized_consequence_epss_disabled_structures = 50,160.73 × $1.2151 = $60,949.60

Dataset 6: Final EPSS Outage Risk (cs_epss_outage_risk)

What is this?

The final EPSS outage risk (in $), the combination of PoF (Dataset 4) × Consequence (Dataset 5). This captures the incremental risk attributable to EPSS: the additional sustained outage risk that would not exist if EPSS were not enabled.

Calculations

For each conductor subset s:

epss_outage_risk_dollarized_s = (prob_epss_failure_s × dollarized_consequence_epss_enabled_conductors)
− (prob_non_epss_failure_s × dollarized_consequence_epss_disabled_conductors)

For each structure subset s:

epss_outage_risk_dollarized_s = (prob_epss_failure_s × dollarized_consequence_epss_enabled_structures)
− (prob_non_epss_failure_s × dollarized_consequence_epss_disabled_structures)

Then:

epss_outage_risk_dollarized = Σ epss_outage_risk_dollarized_s (all 23 subsets)

Example: vegetation_branch (conductor subset)

From Dataset 4:
prob_epss_failure = 0.027176
prob_non_epss_failure = 0.026661

From Dataset 5:
dollarized_consequence_epss_enabled_conductors = 203,805.39
dollarized_consequence_epss_disabled_conductors = 73,821.95
Calculation:
risk_epss = 0.027176 × 203,805.39 = 5,538.67
risk_non_epss = 0.026661 × 73,821.95 = 1,968.15
epss_outage_risk_dollarized_vegetation_branch = 5,538.67 − 1,968.15 = $3,570.53

Example: animal bird (structure subset)

From Dataset 4:
prob_epss_failure = 0.003095
prob_non_epss_failure = 0.002971

From Dataset 5:
dollarized_consequence_epss_enabled_structures = 215,592.45
dollarized_consequence_epss_disabled_structures = 60,949.60

Calculation:
risk_epss = 0.003095 × 215,592.45 = 667.29
risk_non_epss = 0.002971 × 60,949.60 = 181.10
epss_outage_risk_dollarized_animal_bird = 667.29 − 181.10 = $486.19

Final Result: OAKLAND K 1103CR188

Column	Value
epss_outage_risk_dollarized	**$23,245.21**

Interpretation:

- The dollarized risk is **$23,245 per wildfire season** - this is the incremental cost attributable to EPSS converting momentary outages into sustained outages.

Sum Across All Subsets → Final Risk

epss_outage_risk_dollarized =
  $174.94 (primary_conductor_line_slap_cause)
+ $1,840.78 (primary_conductor_wire_down_cause)
+ $656.65 (primary_conductor_other_cause)
+ $100.04 (third_party_balloon)
+ $403.71 (third_party_other)
+ $3,570.53 (vegetation_branch)
+ $2,467.83 (vegetation_trunk)
+ $1,523.69 (vegetation_other)
+ $6,795.42 (other_equipment_type)
+ $288.70 (secondary_conductor)
+ $53.09 (capacitor_bank_equipment_cause)
+ $0 (dpd_equipment_cause)
+ $406.41 (fuse_equipment_cause)
+ $1,026.24 (support_structure_equipment_cause)
+ $472.97 (support_structure_electrical_cause)
+ $0 (switch_equipment_cause — zeroed)
+ $0 (transformer_equipment_cause — zeroed)
+ $0 (transformer_equipment_leaking — zeroed)
+ $0 (voltage_regulator_equipment_cause)
+ $486.19 (animal_bird)
+ $1,805.89 (animal_squirrel)
+ $90.91 (animal_other)
+ $1,081.23 (third_party_vehicle)

= $23,245.21

Background
This supplemental excel file supports this Workpaper EPSS Toy Problem (Attach. B, WP016A) by providing example data that traces how raw WDRM model outputs flow through six datasets to calculate final circuit segment EPSS outage risk. This file includes examples for three circuit segments representing high, medium, and low risk levels.

PSPS TOY PROBLEM

WP017A – PSPS Toy Problem

A. PSPS Risk Calculation Flow - Circuit Segment Level

Analysis for Example Circuit Segment: COARSEGOLD 21025380 (Low Risk Category)

1. Overview

This guide shows how data flows from raw PSPS customer events to final circuit segment PSPS outage risk through 4 datasets.

Attachment: The supplemental excel file, PSPS Toy Problem Calculations (Attach. B, WP017B), supports this Workpaper (Attach. B, WP017A) by providing example data that traces how raw PSPS outage event data flows through four datasets to calculate final circuit segment PSPS outage risk. Attach. B, WP017B includes examples for three circuit segments representing high, medium, and low risk levels, classified along two dimensions: the expected number of PSPS events per wildfire season (based on historical data) and the typical customer-minutes of outage per such event. Please reference the Index sheet in the supplemental excel file to identify the corresponding sheets for each risk-level example.

Note, this workpaper provides a detailed walkthrough of the low-risk example (COARSEGOLD 21025380), while the supporting excel file contains the corresponding inputs and outputs for all three risk-level examples.

PSPS Lookback Period: 7 years (2018-2024)

2. Calculation Flow:

Dataset 1: Base SPID Events (psps_spid_events)
↓ (aggregate by event + apply normalization)
Dataset 2: Event Totals (cs_risk_per_event)
↓ (apply mileage-weighted distribution)
Dataset 3: Risk Distribution (coefficients)
↓ (sum all incoming risk)
Dataset 4: Final Circuit Segment Risk (psps_cs_risk_aggregated)

B. Dataset 1: Base SPID Events (psps_spid_events)

1. What is this?

Raw customer events - each time a customer experienced a PSPS event.

One row = One customer experiencing one PSPS event.

This is a foundational dataset that demonstrates:

- Which customers were affected
- Which events they experienced
- How long they were out
- Their critical customer weighting

2. Key Columns

Column	Description
service_point_id	Unique customer identifier
wdrm_v4_cs_name	Circuit segment the customer is on
event_name	PSPS event identifier
lookback_event_date	Date of the PSPS event
total_outage_duration_hours	Hours the customer was out of power
customer_class	RES, Non-RES
critical_customer_type	Type of critical customer (TT1, Medical_Baseline, etc.)
critical_customer_weighting	Impact multiplier (1, 2, 5, or 100)

3. Example Rows

Regular Residential Customer:

service_point_id	event_name	customer_class	critical_type	weighting	outage_hours
60913878	10132018_2024Q4LB	RES	Regular Customer	1	17.5
60913878	10262019_2024Q4LB	RES	Regular Customer	1	19.5

Critical Commercial Customer:

service_point_id	event_name	customer_class	critical_type	weighting	outage_hours
1138288383	10132018_2024Q4LB	Non-RES	TT1	100	17.5
1138288383	10262019_2024Q4LB	Non-RES	TT1	100	19.5

C. Dataset 2: Event Totals (cs_risk_per_event)

1. What is this?

Each PSPS event's total impact on each circuit segment, with critical customer weights normalized.
One row = One circuit segment experiencing one PSPS event

2. Calculations

This dataset performs **THE KEY NORMALIZATION STEP** that adjusts critical customer impacts back to standard economic levels.

a. Step 1: Get Cost Per Minute (Value of Service)

IF customer_class = "RES" THEN cmi_cost = $0.08 per minute
IF customer_class = "Non-RES" THEN cmi_cost = $23.11 per minute

b. Step 2: Calculate Individual Customer Costs

For each customer in each event:

total_outage_duration_minutes = total_outage_duration_hours × 60
unweighted_cost_per_customer_event = total_outage_duration_minutes × cmi_cost
customer_cost_per_minute = cmi_cost × critical_customer_weighting
weighted_cost_per_customer_event = total_outage_duration_minutes × customer_cost_per_minute

c. Step 3: Calculate Global Normalization Factor (ONCE for all data)

This is calculated ONCE across ALL customers on ALL circuit segments in ALL events:
TOTAL_UNWEIGHTED_CUSTOMER_COST =
SUM(unweighted_cost_per_customer_event)
[across every customer, every event, every circuit segment]

TOTAL_WEIGHTED_CUSTOMER_COST = SUM(weighted_cost_per_customer_event)
[across every customer, every event, every circuit segment]
normalization_factor = TOTAL_UNWEIGHTED_CUSTOMER_COST / TOTAL_WEIGHTED_CUSTOMER_COST
Purpose: This factor adjusts critical customer impacts back down to represent actual economic cost. Without this, a single critical customer with 100× weighting would make their circuit segment appear 100× riskier than it actually is.

d. Step 4: Apply Normalization to Each Customer

customer_cost_per_event = weighted_cost_per_customer_event × normalization_factor

This is the normalized cost - it accounts for critical customer importance but doesn't artificially inflate total system risk.

e. Step 5: Aggregate by Circuit Segment and Event

For each circuit segment, for each event, sum across all customers:
cmi_of_event_on_cs = SUM(total_outage_duration_minutes)
unscaled_cost_of_event_on_cs = SUM(customer_cost_per_event)
count_spids_of_event_on_cs = COUNT(DISTINCT service_point_id)

f. Example: Event 10262019_2024Q4LB on COARSEGOLD 21025380

All 227 customers affected, each out for 19.5 hours = 1,170 minutes

1) Step 1: Individual Customer Costs

Regular RES Customer (60913878):
total_outage_duration_minutes = 19.5 × 60 = 1,170 minutes
unweighted_cost = 1,170 × $0.08 = $93.60
customer_cost_per_minute = $0.08 × 1 = $0.08
weighted_cost = 1,170 × $0.08 = $93.60

Critical Non-RES Customer (1138288383, TT1, 100× weighting):
total_outage_duration_minutes = 19.5 × 60 = 1,170 minutes
unweighted_cost = 1,170 × $23.11 = $27,038.70
customer_cost_per_minute = $23.11 × 100 = $2,311
weighted_cost = 1,170 × $2,311 = $2,703,870

2) Step 2: Global Normalization Factor

Calculated across the entire system (all circuit segments, all events, all customers):
TOTAL_UNWEIGHTED_CUSTOMER_COST = (sum of all unweighted costs across entire system)
TOTAL_WEIGHTED_CUSTOMER_COST = (sum of all weighted costs across entire system)
normalization_factor = TOTAL_UNWEIGHTED / TOTAL_WEIGHTED
**Note, this global normalization factor is currently equal to 0.0846*

3) Step 3: Apply Normalization

Regular RES Customer (60913878):
customer_cost_per_event = $93.60 × 0.08 (sample value) = $7.49

4) Step 4: Aggregate by Event

For Event 10262019_2024Q4LB on COARSEGOLD 21025380:
cmi_of_event_on_cs = 227 customers × 1,170 minutes = 265,590 minutes
unscaled_cost_of_event_on_cs = Sum of all 227 customer_cost_per_event values = $691,934
count_spids_of_event_on_cs = 227

3. **Result for Both Events:**

wdrm_v4_cs_name	event_name	event_date	count_customers	total_cmi	total_cost
COARSEGOLD 21025380	10262019_2024Q4LB	10/27/2019	227	265,590	$691,934
COARSEGOLD 21025380	10132018_2024Q4LB	10/15/2018	227	238,350	$620,966

Interpretation:

- Event 10262019 had the highest economic impact: $691,934
- This represents the normalized cost after adjusting for critical customer weights
- Average impact per customer: $691,934 / 227 = $3,048

4. Dataset 3: Risk Distribution (coefficients)

a. What is this?

How risk flows between circuit segments using mileage-weighted coefficients.
One row = One directional risk flow between two circuit segments in one event

b. Key Concept

When a circuit segment has risk, it's redistributed among electrical ancestors based on their HFTD/HFRA miles within the event polygon. This represents the "circuit-experienced" risk - the actual risk a segment faces considering upstream electrical dependencies.

c. Calculations

1) Step 1: Identify Ancestors

For each circuit segment, identify its electrical ancestors (upstream segments in the electrical path).

COARSEGOLD 21025380 has ancestors including:

- COARSEGOLD 21025380 (itself)
- COARSEGOLD 2102CB (upstream parent)
- COARSEGOLD 210210330 (upstream parent)
- Other upstream segments.

2) Step 2: Identify Segments in Event Polygon

For each event, identify which circuit segments have HFTD/HFRA miles within the event's geographic polygon.

Event 10262019_2024Q4LB polygon includes:

- COARSEGOLD 21025380: 14.00 miles in HFTD/HFRA
- COARSEGOLD 2102383092: 0.32 miles in HFTD/HFRA
- COARSEGOLD 210210330: 9.76 miles in HFTD/HFRA
- COARSEGOLD 2102CB: 14.04 miles in HFTD/HFRA
- Total = 38.13 miles

3) Step 3: Calculate Mileage-Weighted Coefficient

For each ancestor that appears in the event polygon:
miles_weighted_coefficient = segment_HFTD_HFRA_miles / total_ancestor_miles_in_event

For Event 10262019_2024Q4LB (COARSEGOLD 21025380's ancestors in polygon):

- COARSEGOLD 21025380: 14.00 / 38.13 = **0.3673** (36.73%)
- COARSEGOLD 2102383092: 0.32 / 38.13 = **0.0084** (0.84%)
- COARSEGOLD 210210330: 9.76 / 38.13 = **0.2561** (25.61%)
- COARSEGOLD 2102CB: 14.04 / 38.13 = **0.3683** (36.83%)
- Sum = 1.0000 ✓

Interpretation: The coefficients sum to 1.0, meaning 100% of the risk from COARSEGOLD 21025380 is distributed among these four ancestors based on their relative HFTD/HFRA exposure.

4) Step 4: Distribute Event Risk

Take the event's total cost from Dataset 2 and distribute it according to coefficients:
cs_risk_by_coefficient = unscaled_cost_of_event_on_cs × miles_weighted_coefficient

cs_CMI_by_coefficient = cmi_of_event_on_cs × miles_weighted_coefficient
From Dataset 2: Event 10262019_2024Q4LB on COARSEGOLD 21025380:

- Total cost: $691,934
- Total CMI: 265,590 minutes

Risk Distribution:

- COARSEGOLD 21025380 receives: $691,934 × 0.3673 = $254,117
- COARSEGOLD 2102383092 receives: $691,934 × 0.0084 = $5,831
- COARSEGOLD 210210330 receives: $691,934 × 0.2561 = $177,173
- COARSEGOLD 2102CB receives: $691,934 × 0.3683 = $254,813
- Total = $691,934 ✓

CMI Distribution:

- COARSEGOLD 21025380 receives: 265,590 × 0.3673 = 97,538 minutes
- COARSEGOLD 2102383092 receives: 265,590 × 0.0084 = 2,231 minutes
- COARSEGOLD 210210330 receives: 265,590 × 0.2561 = 68,014 minutes
- COARSEGOLD 2102CB receives: 265,590 × 0.3683 = 97,807 minutes
- Total = 265,590 ✓

d. Understanding Direction: FROM_THIS_CS vs TO_THIS_CS

The coefficients dataset shows bidirectional risk flows:

FROM_THIS_CS: Risk that originates from the selected circuit segment and flows to ancestors

- Shows how the selected segment's customer impacts get distributed upstream
- The "related_cs" column shows which ancestors receive the risk

TO_THIS_CS: Risk that flows into the selected circuit segment from other segments

- Shows how other segments (including itself and downstream segments) contribute risk
- The "related_cs" column shows which segments are sending risk

Key Insight: A circuit segment can receive risk from:

1. Itself (if it was in the event polygon)
2. Downstream segments (segments that are electrically downstream but within the same event polygon)

e. Example: FROM_THIS_CS (Self-Distribution)

Event 10262019_2024Q4LB: COARSEGOLD 21025380 → COARSEGOLD 21025380 (to itself)
The segment keeps a portion of its own risk based on its coefficient.

selected_cs	related_cs	event	direction	segment_miles	total_miles	coefficient	distributed_risk	distributed_cmi
COARSEGOLD 21025380	COARSEGOLD 21025380	10262019_2024Q4LB	FROM_THIS_CS	14.00	38.13	0.3673	$254,117	97,538

f. Example: FROM_THIS_CS (Full Distribution to Single Ancestor)

Event 10132018_2024Q4LB: COARSEGOLD 21025380 → COARSEGOLD 2102CB
In this event, only COARSEGOLD 2102CB was in the event polygon (not COARSEGOLD 21025380 itself).

From Dataset 2: Event 10132018_2024Q4LB on COARSEGOLD 21025380:

- Total cost: $620,966
- Total CMI: 238,350 minutes

selected_cs	related_cs	event	direction	segment_miles	total_miles	coefficient	distributed_risk	distributed_cmi
COARSEGOLD 21025380	COARSEGOLD 2102CB	10132018_2024Q4LB	FROM_THIS_CS	7.00	7.00	1.0	$620,966	238,350

Key Insight: In this event, COARSEGOLD 21025380 was NOT in the event polygon, only COARSEGOLD 2102CB was. Therefore, 100% of COARSEGOLD 21025380's customer impacts flow to that single ancestor.

g. Example: TO_THIS_CS (Incoming Risk from Self)

Event 10262019_2024Q4LB: COARSEGOLD 21025380 → COARSEGOLD 21025380 (receiving its own risk)

selected_cs	related_cs	event	direction	segment_miles	total_miles	coefficient	distributed_risk	distributed_cmi
COARSEGOLD 21025380	COARSEGOLD 21025380	10262019_2024Q4LB	TO_THIS_CS	14.00	38.13	0.3673	$254,117	97,538

Same values as FROM_THIS_CS: When a segment distributes risk to itself, it appears in both FROM and TO directions with the same values.

h. Example: TO_THIS_CS (Incoming Risk from Downstream Segment)

Event 10262019_2024Q4LB: COARSEGOLD 210210610 → COARSEGOLD 21025380

COARSEGOLD 210210610 is a downstream segment that also had customers affected in this event. Its risk gets distributed to ancestors, including COARSEGOLD 21025380.

COARSEGOLD 21025380's miles in event polygon: 14.00 miles
Total ancestor miles for COARSEGOLD 210210610 in this event: 39.58 miles
Coefficient = 14.00 / 39.58 = 0.3539 (35.39%)

Risk received from COARSEGOLD 210210610: $68,812
COARSEGOLD 21025380 receives: $68,812 × 0.3539 = $24,350

selected_cs	related_cs	event	direction	segment_miles	total_miles	coefficient	distributed_risk	distributed_cmi
COARSEGOLD 21025380	COARSEGOLD 210210610	10262019_2024Q4LB	TO_THIS_CS	14.00	39.58	0.3539	$24,350	11,415

Interpretation: Of all the risk generated by customers on COARSEGOLD 210210610, 35.39% flows to COARSEGOLD 21025380 because COARSEGOLD 21025380 represents 35.39% of the HFTD/HFRA miles among COARSEGOLD 210210610's ancestors within this event polygon.

5. Dataset 4: Final Circuit Segment Risk (psps_cs_risk_aggregated)

a. What is this?

The total annual circuit-experienced risk for each circuit segment after all mileage-weighted distributions.

One row = One circuit segment

b. Calculations

1) Sum All Incoming Risk

From Dataset 3, for each circuit segment, sum only the TO_THIS_CS rows across all events:
total_risk_across_all_events = SUM(cs_risk_by_coefficient WHERE direction = 'TO_THIS_CS')
total_cmi_across_all_events = SUM(cs_CMI_by_coefficient WHERE direction = 'TO_THIS_CS')

2) Annualize

annual_psps_risk_unscaled = total_risk_across_all_events / 7 years
annual_psps_CMI = total_cmi_across_all_events / 7 years

Why only TO_THIS_CS?

- FROM_THIS_CS shows risk flowing OUT to other segments
- TO_THIS_CS shows risk flowing IN to this segment
- Final circuit-experienced risk = total incoming risk only

c. Example: COARSEGOLD 21025380

From Dataset 3, TO_THIS_CS rows:

1) Event 10262019_2024Q4LB:

1. From COARSEGOLD 21025380 (self):
    a. Risk: $36,302 * 7 = 254,117
    b. CMI: 13,934 * 7 = 97,539 customer-minutes
2. From COARSEGOLD 210210610 (downstream):
    a. Risk: $24,350 × 7 = $170,450
    b. CMI: 11,415 × 7 = 79,905 customer-minutes
3. From COARSEGOLD 21025722 (downstream):
    a. Risk: $11,693 × 7 = $81,851
    b. CMI: 3,811 × 7 = 26,677 customer-minutes

Note: Dataset 3 shows annualized values.

2) Sum Across All Events:

COARSEGOLD 21025380 only receives risk from 1 event (10262019_2024Q4LB):
total_risk_all_events = $254,117 + $170,450 + $81,851 = $506,418
total_cmi_all_events = 97,538 + 79,905 + 26,677 = 204,120 minutes

3) Annualize:
annual_psps_risk_unscaled = $506,418 / 7 = $72,345
annual_psps_CMI = 204,120 / 7 = 29,160 customer-minutes

Result:

wdrm_v4_cs_name	annual_psps_risk_unscaled	annual_psps_CMI
COARSEGOLD 21025380	$72,345	29,160

Interpretation:

- This circuit segment experiences $72,345 in annual PSPS risk
- This includes:
  - Risk from its own customers ($36,302 annual)
  - Risk flowing in from downstream segment COARSEGOLD 210210610 ($24,350 annual)
  - Risk flowing in from downstream segment COARSEGOLD 21025722 ($11,693 annual)
- Total circuit-experienced impact: 29,160 customer-minutes per year

Background
This supplemental excel file supports Workpaper PSPS Toy Problem (Attach. B, WP017A) by providing example data that traces how raw PSPS customer events flow through four datasets to calculate final circuit segment PSPS outage risk. This file includes examples for three circuit segments representing high, medium, and low risk levels.

Worksheet	**Word Doc Reference**	**Data Set Name**

1 Executive Summary

The Enhanced Powerline Safety Settings (EPSS) Risk Model provides the dollarized risk of outages on circuit segments that occur during periods in which EPSS is enabled. It is used as a component of the overall Outage Risk Model, which is used by the Electrical Undergrounding Plan (EUP) project for prioritizing high risk circuit segments for undergrounding. The EPSS Risk Model is a deterministic mathematical model and calculates EPSS likelihood, which estimates the expected number of outages (in minutes per year) when EPSS is enabled, and EPSS consequence, which quantifies the expected cost (in dollars per minute of interruption) of an outage on a circuit segment that is calculated by the number of affected customers and value of service.

The EPSS Risk Model was developed to meet the requirements of SB884, which governs the regulation of the EUP filing, the guidelines for which were developed by the Office of Energy Infrastructure and Safety (OEIS). It also serves as a component of PG&E's broader strategy to mitigate wildfire risk while maintaining continuous and reliable electrical service to its customers.

2 Introduction

The EPSS Risk Model estimates the dollarized risk of outages on circuit segments during periods in which EPSS is enabled, including the risk associated with downstream outages. It is used as a component of the Outage Risk Model to support wildfire season planning and regulatory reporting, helping assess the tradeoff between wildfire mitigation and customer reliability impacts. While the model is deterministic and does not incorporate machine learning techniques, it provides a structured framework for evaluating outage risk on circuit segments, including downstream impacts. This document outlines the modeling approach, source data, and resulting probability predictions used in the EPSS Risk Model. It is intended to provide a high-level overview for a general audience, emphasizing conceptual understanding rather than detailed mathematical or scientific exposition.

Along with the PSPS Risk Model, the EPSS Risk Model is one of two models that feed into the Outage Risk Model. These models evaluate the risk associated with circuit segments using a circuit-based approach quantifying the dollar value of risk that could be avoided if a circuit segment was undergrounded and thereby excluded from exposure to the two preventative service outage programs.

2.1 EPSS Risk Model Overview

The EPSS program is a wildfire mitigation strategy in which EPSS device settings are enabled during elevated weather conditions. When active, the system automatically de-energizes power lines within one-tenth of a second when a fault is detected, reducing the risk of ignition. The EPSS Risk Model estimates the reliability risk, quantified in dollars, associated with sustained outages that occur under these conditions. The EPSS Risk Model is a deterministic mathematical model that leverages outputs from the Wildfire Distribution Risk Model (WDRM), developed by the Wildfire Data Science team, and the Distribution Reliability Value Model, developed by the Integrated Grid Planning team. The model calculates EPSS likelihood, which estimates the expected number of outages (in minutes/year) when EPSS is enabled, and EPSS consequence, which quantifies the expected cost (in dollars per minutes of interruption) of an outage on a circuit segment that is calculated by the number of affected customers and value of service.

This document describes version 1 of the EPSS Risk Model. Future versions will be developed around the Wildfire Mitigation Plan (WMP) reporting cycle and will be released in conjunction with the WDRM.

2.2 Document Suite

This documentation is part of the documentation suite for the Outage Risk Model developed in support of the EUP project:

- Outage Risk Model v1.1 Documentation
- EPSS Risk Model v1.3 Documentation (this document)
- PSPS Risk Model v1.3 Documentation

3 EPSS Risk Model Derivation

3.1 Data Inputs

The EPSS Risk Model relies on several data sources, described below. The specific applications of these sources are explained throughout the document.

The WDRM v4 provides circuit segments mapping (based on the January 1st, 2023 vintage) and probability of failure for each WDRM subset. In addition, WDRM subsets are also used to estimate the effectiveness of undergrounding power lines and alternative mitigations. Further details on WDRM v4, including methodology and subset models are available in the supporting document titled WDRM v4 Documentation.

The Distribution Reliability Value Model assesses the societal cost of service disruptions caused by asset failures. It produces a quantitative output called Distribution Reliability Consequence that determines the consequence based on both customer and grid-level costs. The model also provides outage duration estimates by equipment categories, which are used as inputs into the EPSS Risk Model.

The Interruption Cost Estimate (ICE) Calculator, developed by Lawrence Berkeley National Laboratory (LBNL) and Resource Innovations, Inc, is a reliability planning tool designed for estimating interruption costs and/or the benefits associated with reliability improvements. The EPSS Risk Model leverages customer power interruption costs from version 2.0 of the ICE Calculator.

3.2 EPSS Risk and Assumptions

The general framework of risk assessment is defined as:

$$Risk = Likelihood \times Consequence$$

For EPSS, this represents the incremental outage (or reliability) risk, quantified in dollars, associated with sustained outages that occur when EPSS is enabled during wildfire season. At the circuit segment level, this is calculated as the difference between the outage risk with EPSS enabled and the outage risk with EPSS disabled:

$$EPSS\_Risk_{cs} = risk\_with\_epss\_enabled_{cs} - risk\_with\_epss\_disabled_{cs}$$

In this context, likelihood reflects the probability of a sustained outage when EPSS is enabled or disabled during wildfire season, while consequence represents the duration and monetary impact of those outages. The resulting risk when EPSS is enabled is:

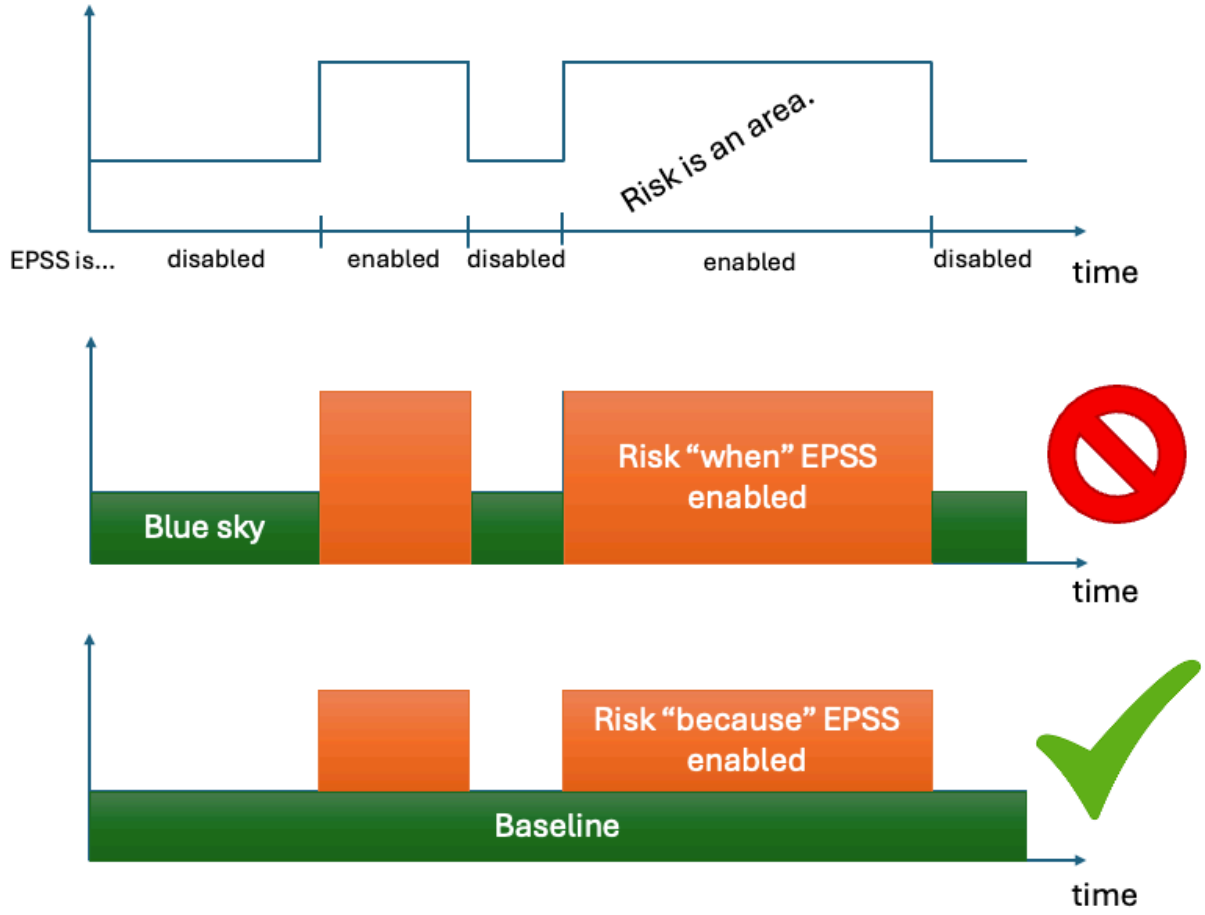

$$risk\_with\_epss\_enabled_{cs} = \sum_{m \in asset\_types} N^{EPSS\_enabled}_{sustained\ outages,m(s),cs} * C^{EPSS\_enabled}_{sustained\ outages,m,cs}$$

Where $N^{EPSS\_enabled}_{sustained\ outages,m(s),cs}$ is the number of expected sustained outages $N_{sustained\ outages}$ (excluding momentary, forced, transformer and switch outages) on circuit segments, cs, during the portions of wildfire season when EPSS is enabled, $EPSS\_enabled$. These outages are grouped according to the WDRM subsets s, which each subset is mapped to an asset type m (additional context is provided in Appendix B). Since this value represents a count over time, it is technically a rate and is also referred to as *likelihood* or *frequency*.

$C^{EPSS\_enabled}_{sustained\ outage,m,cs}$ is the consequence of a sustained outage $C_{sustained\ outage}$ (excluding momentary, forced, transformer and switch outages) should it occur on the circuit segment cs, from each of the IGP asset types m.

The risk, if EPSS were disabled, is similar to when EPSS is enabled, except for one vital nuance. The term $N^{EPSS\_disabled}_{sustained\ outages,m(s),cs}$ does *not* refer to outages expected during periods when EPSS was actually *disabled*. Instead, it estimates the number of outages that would have occurred during EPSS *enabled* periods if EPSS had *not* been enabled. For example, if EPSS is enabled on a circuit segment for 80% of wildfire season, $N^{EPSS\_enabled}$ reflects the expected outage count during that time, and $N^{EPSS\_disabled}$ reflects the expected outage count during that same time, assuming *EPSS had been disabled.* The remaining 20% of the season, when EPSS was disabled, is excluded from this analysis. This approach isolates the incremental outage risk attributable to EPSS enablement. As illustrated in Figure 1: Incremental Risk from EPSS Enablement, the model decomposes total EPSS outage risk into two components: the annual baseline risk that would exist if EPSS were disabled (the green horizontal rectangle), and the incremental risk introduced by enabling EPSS (the orange boxes stacked above). The full height of the stacked boxes reflects the total risk when EPSS is enabled. The portion overlapping the horizontal rectangle represents risk that would have occurred regardless. The difference between the “risk *because* EPSS is enabled” boxes, is the focus of this model.

Figure 1: Incremental Risk from EPSS Enablement

3.3 EPSS Likelihood

The EPSS likelihood represents the likelihood of a sustained outage occurring on a circuit segment when EPSS is enabled. It is derived from the probability of failures in the WDRM, and mapped to asset types, such as conductors and support structures. The calculation also incorporates historical EPSS enablement data, filtered for High Fire Threat Districts (HFTD) and/or High Fire Risk Areas (HFRA). This produces a likelihood value that reflects the expected number of sustained outages per year during EPSS-enabled periods.

As of the Oct 2025 methodology update, transformer and switch-related WDRM subset probabilities are set to zero for EPSS outage risk estimation because these failure modes are considered independent of EPSS operations.

3.3.1 WDRM: Probability of Failure

The EPSS likelihood calculation aggregates probability of failure from all WDRM subsets. While the WDRM shows that outages don't always cause ignitions and failures don't always cause outages, the EPSS Risk Model assumes every failure results in an outage. Therefore, in this analysis, the probability of failure is used interchangeably for outage rate. For asset-based models in the WDRM, this probability is mapped to the support structure. For pixel-based models, the probability of failure for each driver is divided by the number of structures per pixel to estimate per-structure risk. Assets and pixels are filtered to include only those located within HFTD/HFRA. This produces a per-structure probability of failure, which is then aggregated across all structures within a circuit segment to estimate EPSS likelihood at the circuit segment level.

$$L_{CS} = \sum_{CS,asset} L_{asset} + \sum_{CS,pixel} \frac{L_{pixel}}{N_{structures}}$$

3.3.2 Circuit Segment Probability of Failure

To estimate EPSS outage risk, two key probabilities are calculated for each circuit segment:

The first is the probability of a sustained outage when EPSS is enabled. This is derived from multiplying the expected number of outages during wildfire season, based on the WDRM, by the fraction of time during which EPSS is enabled (on each circuit). No adjustment is made for sustained versus momentary outages, as nearly all outages occurring during EPSS activation are sustained. Mathematically, this is expressed as:

$$N^{EPSS\_enabled}_{sustained\ outages,s,cs} = f_{EPSS_{enabled},cs} * N_{outages,s,cs}$$

Where:

- $N_{outages,s,cs}$ is the annual expected outage count from each subset s on the circuit segment cs.
- $f_{EPSS_{enabled},cs}$ is the fraction of wildfire season during which EPSS is enabled on the circuit segment cs.

The second is a counterfactual (unrealized) probability, an estimate of the number of sustained outages that would have occurred during EPSS-enabled periods if EPSS had

not been active. This probability is calculated by multiplying the expected outage count during wildfire season by the fraction of time that EPSS is enabled on each circuit and by the proportion of outages that are historically sustained during wildfire season had EPSS been disabled. The expression is:

$$N^{EPSS\_disabled}_{sustained\ outages,s,cs} = f_{EPSS\_enabled,cs} * N_{outages,s,cs} * f_{sustained,s}$$

Where, the additional term, $f_{sustained,s}$ represents the ratio of sustained outages to total outages for subset s, based on historical data.

To complete the risk estimation, a baseline probability of sustained failure is calculated for the entire year, representing conditions as though EPSS were not in place. This annual probability, expressed in outages per year and potentially exceeding 1, is intended to reflect sustained outage risk across all seasons. Since the WDRM provides failure probability models only for the wildfire season (June through November), assumptions are required to extend the analysis to the winter season (December through May).

To estimate the annual probability of sustained outages, the wildfire season failure probability from the WDRM is multiplied by 2.5 (further explained in Appendix A), then adjusted by the historical proportion of sustained outages, and finally, normalized into outages/circuit-mile.

3.3.2.1 EPSS Historical Enablement

EPSS enablement is determined daily on elevated weather conditions and is primarily enabled during the wildfire season. Although EPSS may be enabled at any time of year, the system is most frequently activated between June and November, what is considered as wildfire season. Enablement occurs at the circuit level, meaning an entire circuit is either enabled or disabled.

For the years 2017-2020, the analysis uses EPSS lookback data developed by the Enterprise Operations Risk Management (EORM) team, which retrospectively estimates EPSS enablement based on current criteria. The year 2021 is excluded from the analysis, as it was a pilot year and does not reflect current EPSS settings or enablement (operational practices).

For 2022 through 2024, actual historical enablement data is used, filtered to include only wildfire season months. While EPSS may have been enabled outside of wildfire season, those instances are excluded to maintain consistency in seasonal risk assessment.

Based on the enablement data described above, the fraction of EPSS enablement for each circuit is calculated as the ratio of total enabled days to total wildfire season days.

$$f_{EPSS_{enabled}} = \frac{total\ enabled\ days_{2017-2024}}{total\ wildfire\ season\ days_{2017-2024}}$$

3.3.2.2 Sustained Outages

Momentary outages occur frequently and are inherent to automatic reclosing operations (particularly when EPSS is not enabled), therefore, the EPSS program primarily impacts sustained outages, defined as those lasting longer than five minutes. These events are tracked and reflected in reliability metrics such as System Average Interruption Duration Index (SAIDI) and System Average Interruption Frequency Index (SAIFI). To isolate sustained outages from total outages, the analysis applies a sustained outage fraction that excludes momentary events. When EPSS is *disabled*, reclosers frequently reestablish current for minor events, such as a small branch falling on the conductor, which creates a momentary outage. When EPSS is *enabled*, the same event will result in a sustained outage due to the disabling of automatic reclosing. As a result, the fraction of sustained outages when EPSS is *enabled* is assumed to be approximately 1, while the fraction of sustained outages when EPSS is *disabled* is based on WDRM subset. This calculation uses historical non-EPSS regular and forced outages during wildfire season in HFTD/HFRA. The sustained outage fraction for each WDRM subset is calculated by dividing the number of sustained outages over the total number of outages.

3.4 EPSS Consequence

EPSS consequence represents the financial impact of a sustained outage occurring on a circuit segment when EPSS is enabled, measured in dollars per minute of interruption. This value is determined by evaluating the number of customers affected by an EPSS outage, in addition to those who would have experienced a normal outage. The calculation also incorporates outage duration data from the IGP Distribution Reliability Value Model and customer interruption costs per minute, also referred to as value of service, sourced from the ICE 2.0 Calculator. Together, these components produce a consequence value that reflects the expected impact of sustained outages during EPSS-enabled periods. The final value is calculated using the following expression:

$$C^{EPSS\_enabled}_{sustained\ outages,m,cs} = D_{sustained\ outage,m,cs} * N^{EPSS\_enabled}_{customers,m,cs} * VOS_{cs}$$

Where m refers to two asset groups: conductor and support structure, represented as $m \in \{conductor, support\ structure\}$.

3.4.1 Impacted Customer Count

To determine the number of customers affected by an EPSS outage, the model evaluates the primary overhead conductor or support structure associated with each EPSS-enabled protective device. This analysis includes both the downstream customer count during EPSS-enabled outages and the customer count associated with conductors and support structures during outages that occur when EPSS is not enabled. This distinction allows the model to compare customer impact resulting from damage to conductor or support structures during EPSS-enabled outages versus non-EPSS outages, thereby identifying the incremental customer count attributable to EPSS activation.

The model then applies a standardized average value of service per EPSS device. This value is based on the mix of customers connected to that device and is calculated using the ICE 2.0 Calculator.

3.4.2 Reliability Consequence Model: Outage Duration

The expected duration of an outage on a circuit segment, $D_{sustained\ outage,m,cs}$ is derived from the IGP Outage Duration model. This model estimates the expected outage duration for each asset based on its type and the kind of protective device located upstream of it. The duration is represented as $d_{a(m,p)}$, where a is the asset, m indicates the asset type (such as conductor or support structure), and p identifies the upstream protective device (including fuse, switch, DPD [dynamic protective device], or breaker).

To calculate the expected outage duration for a specific asset type on a circuit segment, the model applies the following formulation:

$$D_{sustained\ outage,m,cs} = \frac{1}{N_{m,cs}} \sum_{\substack{a \in cs \\ of\ type\ m}} d_a$$

In this equation, $N_{m,cs}$ represents the number of individual assets of type m on circuit segment cs. For example, if the asset type is support structures, the model sums the estimated outage durations for all support structures within the circuit segment and

divides by the total number of support structures present on that segment. Each support structure's outage duration is determined by the type of upstream protective device, resulting in one of four possible values measured in minutes.

The model also estimates the number of customers impacted by an outage under two scenarios: when EPSS is enabled and when it is not. The expected number of customers affected when EPSS is enabled is denoted as:

$$N_{customers,m,cs}^{EPSS\_enabled}$$

In this scenario, the outage is attributed to the nearest EPSS-enabled device, which may be located upstream of the nearest protective device that would normally isolate the fault. This results in a broader set of customers being impacted, as the outage is traced to a higher-level device in the system.

When EPSS is not enabled, the outage is contained by the nearest protective device. The number of customers impacted in this case reflects those downstream of that device and is represented as:

$$N_{customers,m,cs}^{EPSS\_disabled}$$

In HFTD/HFRA, the average ratio of customers impacted under EPSS-enabled versus EPSS-disabled conditions varies significantly across circuit segments. This ratio is approximately 2.15 and is represented as:

$$N_{customers,m,cs}^{EPSS\_enabled} \,/\, N_{customers,m,cs}^{EPSS\_disabled}$$

The final component is VOS_{cs}, the value of service for customers in a given circuit segment. This value is calculated as the weighted average of the value of service across customer classes, based on the number of customers in each class:

$$VOS_{cs} = \sum_{c \in \{RES, NON-RES\}} VOS_c * \frac{N_{c,cs}}{N_{cs}}$$

As stated in previous sections, the EPSS Risk Model version 1 leverages value of service from the ICE 2.0 Calculator, which categorizes customers into two classes, Residential and Non-Residential for both HFTD/HFRA and Non-HFTD/Non-HFRA. For Residential customers, the value of service, VOS_c is $0.08 per customer-minute of interruption while for Non-Residential customers, it is $23.11 per customer-minute of interruption. In this equation, $N_{c,cs}$ refers to the number of customers of class c on the circuit segment cs, and N_{cs} is the number of customers on that circuit segment.

3.5 Likelihood and Derived Consequence for EUP

For EUP reporting, we define likelihood as total outage-minutes during EPSS-enabled periods (i.e., probability × duration), and we derive consequence as dollarized risk divided by likelihood.

The EPSS risk is defined as the incremental risk of outages that exceed the standard outage risk when EPSS is not enabled. This includes outages that were mitigated due to EPSS being active, by considering the likelihood of those outages occurring if EPSS had not been enabled during the same time. In contrast, the EPSS likelihood reported for the EUP reflects the full likelihood of an EPSS outage, encompassing all outages that would have occurred during that time regardless of EPSS activation. This approach ensures a comprehensive representation of outage likelihood, though it introduces a potential mismatch in risk and likelihood reporting.

Given that OEIS defines likelihood to include outage duration, the EUP framework removes outage duration from the consequence calculation. At the circuit segment level, this adjustment is implemented by multiplying the previously defined likelihood by outage duration, while consequence is calculated by dividing risk by likelihood.

It is important to note that consequence is calculated at the circuit segment level but cannot be aggregated to higher levels using a simple summation. Instead, consequence must be derived at the portfolio or system levels by dividing the aggregated risk across all relevant circuit segments by the aggregated likelihood across those same segments. This method accounts for the varying number of event probability results associated with each segment. Attempting to sum individual consequence values and the total likelihood directly would not yield an accurate representation of total risk. To resolve this mathematical inconsistency, the effective consequence for an aggregated composite is back-calculated as a likelihood-weighted value by dividing the total risk for the portfolio or system by the total likelihood for that same group of segments.

3.6 Customer-Experienced vs Circuit-Based Risk

“Circuit-Experienced” Risk refers to the risk attributed to the entire circuit resulting from failures that occur on a specific circuit segment. Whereas “Customer-Experienced” Risk captures the risk experienced by customers located on a circuit segment due to failures occurring anywhere along the full circuit. The EPSS Risk Model inherently produces circuit-experienced risk values. This is because EPSS devices are not mapped one-to-one with circuit segments; instead, an EPSS zone, the area protected by a single EPSS device, may span multiple circuit segments. When an EPSS outage occurs on a given circuit segment, it may affect customers located outside of that circuit segment but still within the same EPSS zone. In such cases, the risk is attributed to the circuit segment where the outage originated, which aligns with the definition of circuit-experienced risk.

4 Model Usage

Per circuit segment, reported outputs include: dollarized risk, annual CMI, likelihood (outage-minutes), consequence ($/minute), and expected outage count (sustained outages).

4.1 Usage

The EPSS Risk Model is applied at the circuit segment level. It is used as a component of the Outage Risk Model during wildfire season planning and regulatory reporting to assess the tradeoff between wildfire mitigation and customer reliability impacts.

4.2 Shelf Life

The EPSS Risk Model is structured around the Wildfire Mitigation Plan (WMP) reporting cycle and is refreshed in conjunction with new releases of the WDRM. With each Outage Program Risk Model version, the inputs will be updated accordingly with the WDRM and input data.

Appendices

Appendix A: Baseline Outage Risk

A baseline probability of sustained failure for the entire year must be calculated to get baseline outage risk, representing conditions as though EPSS were not in place. This annual probability, expressed in outages per year and potentially exceeding 1, is intended to reflect sustained outage risk across all seasons. Since the WDRM provides failure probability models only for the wildfire season (June through November), assumptions are required to extend the analysis to the winter season (December through May).

An initial approach to estimating annual outage risk involved comparing WDRM wildfire season models with prototype full-year models available for a limited number of subsets. However, this method was ultimately discarded due to significant compatibility issues between the two model types. In several instances, the winter outage probabilities derived from the full-year models were negative, an outcome that is clearly infeasible and indicative of underlying model misalignment.

As an alternative, the analysis shifted to examining counts at the circuit level, independent of subset distinctions. The objective was to determine whether a correlation existed between winter and wildfire season outages. While the drivers of outages in these two seasons differ substantially, making it plausible for a circuit to be highly vulnerable in winter but not during wildfire season, a moderate correlation of approximately 65% was observed. Based on this relationship, a multiplier of 1.5 was derived, indicating that circuits experience roughly 1.5 times more outages in winter than during wildfire season. To estimate the annual probability of sustained outages, the wildfire season failure probability from the WDRM is multiplied by 2.5 (accounting for both seasons), and then further adjusted by the historical proportion of sustained outages (~83%), thereby excluding momentary outages from the final estimate. Outages are then normalized by total circuit mileage to calculate outage density (outages per mile) for each.

Appendix B: Mapping WDRM Subsets to IGP Asset Types

Twenty-two WDRM subsets are categorized according to their association with either conductor or support structure failures. These groupings are used to calculate outage duration using the IGP model. Table 1: Example Mapping of WDRM Subsets to Asset Types illustrates this mapping using the example circuit segment ORO FINO 11012022. In the figure, the first ten subsets (highlighted in yellow) are mapped to conductors, while the remaining twelve subsets (highlighted in blue) are mapped to support structures.

2 Introduction

The Outage Program Risk Model (also known as the Outage Risk Model or Reliability Model) quantifies the reliability impacts of two wildfire mitigation programs: Enhanced Powerline Safety Settings (EPSS) and Public Safety Power Shutoff (PSPS). It estimates the dollarized outage risk on circuit segments during EPSS-enabled periods and PSPS events, including downstream outage impacts. These models evaluate the risk associated with circuit segments using a circuit-based approach that quantifies the dollar value of risk potentially avoided if a circuit segment were undergrounded and thereby excluded from exposure to the two preventative service outage programs. While the model is deterministic and does not incorporate machine learning techniques, it provides a structured framework for evaluating outage risk on circuit segments, including downstream impacts.

2.1 Purpose

The Outage Program Risk Model was developed to meet the requirements of SB884. The Electrical Undergrounding Plan (EUP) uses these risk estimates to prioritize high-risk circuit segments for undergrounding. The model also supports wildfire season planning and regulatory reporting by evaluating the tradeoff between wildfire risk reduction and customer reliability impacts. Additionally, the Outage Program likelihood serves as the basis for establishing the High Frequency Outage Program threshold, which identifies additional circuit segments considered to have a significantly high likelihood of frequent or prolonged disruption of service to customers and are thus eligible for undergrounding or alternative mitigations.

This document outlines the modeling approach, source data, and resulting probability predictions used in the version 1 Outage Program Risk Model. It is intended to provide a high-level overview for a general audience, emphasizing conceptual understanding rather than detailed mathematical or scientific exposition.

2.2 EPSS and PSPS Risk Models Overview

The EPSS program is a wildfire mitigation strategy in which EPSS device settings are enabled during elevated weather conditions. When active, the system automatically de-energizes power lines within one-tenth of a second when a fault is detected, reducing the risk of ignition. The EPSS Risk Model estimates the reliability risk, quantified in dollars, associated with sustained outages that occur under these conditions. The model calculates EPSS likelihood, which estimates the expected number of outages (in minutes/year) when EPSS is enabled, and EPSS consequence, which quantifies the expected cost (in dollars per minute of interruption) of an outage on a circuit segment that is calculated by the number of affected customers and value of service.

Meanwhile, the PSPS Risk Model estimates the dollarized risk of PSPS outages at the circuit segment level, accounting for both direct impacts and the risk of causing downstream outages. The model incorporates multiple factors related to likelihood and consequence of PSPS events. Likelihood factors include historical presence within a spatiotemporal PSPS event polygon, minutes of resulting outage, miles of exposed circuit, and circuit geometry both upstream and downstream. Consequence factors include the number of customers affected by historical outages and customer segmentation factors and service cost for each affected customer.

For more detailed information on the EPSS Risk Model and PSPS Risk Model, see their respective documentation.

2.3 Document Suite

This documentation is part of the documentation suite for the Outage Risk Model developed in support of the EUP project:

- Outage Risk Model v1.1 Documentation (this document)
- EPSS Risk Model v1.3 Documentation
- PSPS Risk Model v1.3 Documentation

3 Outage Program Risk Model Derivation

The Outage Program Risk Model calculates Outage Program likelihood, which estimates the expected number of outage minutes per year when either EPSS is enabled or a PSPS event is initiated. It also quantifies the Outage Program consequence, representing the expected cost of an outage on a circuit segment in terms of dollars per minute of interruption. This cost is derived from the characteristics of affected customers and the associated value of service. While these risk components characterize the frequency and impact of outages, overall Outage Program risk is derived separately through aggregation of the risk outputs from the EPSS and PSPS Risk Models, resulting in an estimate of the expected financial impact of outage programs on circuit segments.

3.2 Outage Program Risk

The Outage Program Risk Model quantifies the risk in dollars resulting from the outages created by two wildfire mitigation programs: EPSS and PSPS. The model leverages risk outputs from the EPSS Risk Model and PSPS Risk Model. Each program's risk is represented in dollars, and the total Outage Program risk is calculated as the sum of the individual risks:

$$Risk_{Outage\ Program} = Risk_{EPSS} + Risk_{PSPS}$$

3.3 Outage Program Likelihood

Outage Program likelihood represents the probability of a sustained outage occurring on a circuit segment when either EPSS is enabled or a PSPS event is initiated. It is defined as the expected number of outage minutes per year attributable to these programs and is calculated by summing the individual likelihoods:

$$Likelihood_{Outage\ Program} = Likelihood_{EPSS} + Likelihood_{PSPS}$$

3.4 Outage Program Consequence

The Outage Program consequence represents the financial impact of a sustained outage occurring on a circuit segment when either EPSS is enabled or a PSPS event is initiated. It is measured in dollars per minute of interruption and is used to estimate the financial impact to customers based on the number and type of customers affected,

as determined by the value of service (VOS) lost. While risk (in dollars) and likelihood (in minutes) can be summed across programs, consequence must be derived by dividing risk by likelihood. Consequence cannot be aggregated directly because it is a normalized measure of outage impact ($/minute), not a measure of total impact. Total financial impact is obtained only after consequence is combined with the corresponding outage duration (likelihood) to calculate risk.

$$Consequence_{Outage\ Program} = \frac{Risk_{Outage\ Program}}{Likelihood_{Outage\ Program}}$$

For the same reason, consequence is determined at the circuit segment level; however, it cannot be combined into higher levels by straightforward summation. Instead, consequence must be derived at the portfolio or system level by dividing the aggregated risk across all relevant circuit segments by the aggregated likelihood across those same segments. This method accounts for the varying number of event probability results associated with each segment.

4 Model Usage

4.1 Usage

The Outage Program Risk Model is applied at the circuit segment level, and it is used as an input into Overall Utility Risk. In addition to its role in risk quantification, the Outage Program likelihood is used to determine eligibility for the High Frequency Outage Program Threshold. Circuit segments that exceed this threshold are considered to have a significantly high likelihood of frequent or prolonged service disruption. The threshold encompasses 1% of primary overhead miles in PG&E's system *and* accounts for up to 10% of Outage Program likelihood by rank.

The Ignition Tail Risk Threshold flag is derived using a similar approach, based on ignition-weighted wildfire consequence. This threshold also represents 1% of primary overhead miles in PG&E's system *and* captures up to 10% of the ignition-weighted wildfire consequence from the WDRM, ranked by score. It identifies circuit segments with significant potential for ignition of a catastrophic wildfire and designates them for special consideration.

4.2 Shelf Life

The Outage Program Risk Model is structured around the Wildfire Mitigation Plan (WMP) reporting cycle and is refreshed in conjunction with new releases of the WDRM. With each Outage Program Risk Model version, the inputs will be updated accordingly with the WDRM and input data.

1 Executive Summary

The Public Safety Power Shutoff (PSPS) Risk Model provides the dollarized risk of PSPS outages on circuit segments, including the risk associated with downstream outages. It is used as a component of the overall Outage Risk Model, which is used by the Electrical Undergrounding Plan (EUP) project for prioritizing high risk circuit segments for undergrounding. The PSPS Risk model is a deterministic mathematical model derived from the customer-experienced outage risk on each circuit segment. In order to reflect the full risk (and thus the value of undergrounding) for each circuit segment, the model incorporates several factors: the segment's historical likelihood of appearing in a PSPS event polygon, its exposed length in miles, the geometry of both its upstream and downstream circuit segments, and the customer base served by all of these interrelated segments.

This model was developed to meet the requirements of SB884, which governs the EUP project. It also serves as a component of PG&E's broader strategy to mitigate wildfire risk while maintaining continuous and reliable electrical service to its customers.

2 Introduction

2.1 Model Overview

The PSPS Risk Model estimates the dollarized risk of PSPS outages at the circuit segment level, accounting for both direct customer impacts and the risk of causing downstream outages. The model uses outage durations that include patrol and restoration time as provided by the PSPS team, and it incorporates only PSPS events with a distribution footprint (Dx-only or Dx+Tx), excluding transmission-only events. The seven-year lookback period combines the formal PSPS Lookback Study (2018–2022) with SCADA-captured PSPS events from 2023-2024, scoped under Plan C (PSPS event used for analysis as defined by the PSPS team).

The PSPS Risk Model is used as a component of the Outage Risk Model during wildfire-season planning and regulatory reporting to assess the tradeoff between wildfire mitigation and customer reliability impacts. It is a deterministic mathematical model with no machine-learning component. PSPS risk on a given circuit segment is modeled as a nonlinear function of likelihood and consequence factors. Likelihood factors include historical presence within a spatiotemporal PSPS event polygon, minutes of resulting outage, miles of exposed circuit, and circuit geometry both upstream and downstream. Consequence factors include the number of customers affected by historical outages, customer segmentation factors, and the service cost for each affected customer.

Along with the EPSS Risk Model, the PSPS Risk Model is one of two models that feed into the Outage Risk Model. These models evaluate the risk associated with circuit segments using a circuit-based, “source-based” approach, quantifying the dollar value of risk that could be avoided if a circuit segment were undergrounded and thereby removed from exposure to the two preventative service-outage programs.

2.2 Document Suite

This document is part of the documentation suite for the Outage Risk Model developed in support of the EUP project:

- Outage Risk Model v1.1 Documentation
- PSPS Risk Model v1.3 Documentation (this document)
- EPSS Risk Model v1.3 Documentation

3 PSPS Risk Model Derivation

This section outlines the PSPS Risk Model, which serves as an input to the broader Outage Risk Model. The current model provides a dollarized risk and outage prediction on each circuit segment based on their historical likelihood of being present in a geo-temporal PSPS event polygon. The model outputs three key predictions for each circuit segment:

1. Dollarized PSPS Circuit-Based Risk
2. Annual PSPS Customer Minutes of Interruption (CMI)
3. Annual PSPS Likelihood

As stated in previous sections, the PSPS Risk Model is a deterministic mathematical model. It uses a rule-based formulation to compute the expected number of sustained outages based on circuit geometry, aggregated customer value-of-service data, and historical PSPS event polygons. The PSPS Risk Model does not involve simulation, machine learning, or statistical inference.

It is also a nonlinear model. Unlike customer-experienced risk, which can be expressed as the product of a separable Likelihood model and Consequence model, there is no possible separable standalone Consequence model for PSPS risk. Instead, Derived Consequence may be used as an equivalent.

3.1 Customer-Experienced vs Circuit-Based Risk

To understand the PSPS Risk model, it is important to make a distinction between *in situ* or "customer-experienced" risk versus source-based or "circuit-based" risk. Many PG&E circuit risk models predict risk from the customer's point of reference, at the location of a potential outage. This *in situ* risk's core relationship is simply the likelihood of an outage event at the location of a given circuit segment multiplied by the dollarized consequence of loss of service to the customers served by that segment. Therefore, the basic customer-experienced risk formula is:

$$Risk_{customer-experienced} = Likelihood \times Consequence$$

This relationship quantifies the predicted loss of value for a given circuit segment. If outages across circuit segments were entirely independent, this same relationship would also express the risk of each circuit segment as a distinct *source* since each segment could only be serviced-energized by its own unique risk factors.

However, circuit segment outages are *not* independent. An outage in an upstream segment will inevitably propagate to all downstream segments. Therefore, to accurately assess the risk reduction achieved by replacing or hardening any segment that may serve as a source of outages, the risk averted at downstream sites must also be factored in.

The PSPS Risk Model is designed to assign a risk value to each circuit segment as a potential *source* of outage, supporting prioritization decisions for undergrounding of circuit segments and segment portfolios. Within a PSPS event, it is common for a circuit segment to have

downstream segments, some included in the event region and others outside, that nonetheless experience outages due to upstream de-energization. The model attributes the customer-experienced risk of these downstream segments across their upstream segments. To avoid bias, this attribution is weighted by the length of exposed circuit upstream.

Attributing this downstream risk to upstream source segments adds nonlinearity to the model. Accordingly, risk is calculated holistically as a nonlinear function of historical likelihood data, circuit geometry, event polygon geometry, and the single-circuit consequence of the circuit segment and all subsequent downstream segments.

Certain circuit segments have zero customers yet intersect PSPS polygons. While they exhibit no onsite customer-experienced risk, they can still serve as upstream sources of downstream outages. These segments are included so their downstream risk can be properly attributed within the circuit-based model.

In addition, the consequence component incorporates updated customer-segmentation practices: Road/Highway SPIDs are excluded from risk and CMI computations, and ICE 2.0 value-of-service rates are unified into one system-wide Residential rate and one systemwide Non-Residential rate (shared by Small and Medium C&I customers), with no HFTD/HFRA split.

3.2 Data Sources

The data sources for this model include:

The PSPS Lookback Study, provided by the PSPS team. This dataset provides seven years of PSPS event data such as event polygons, outage duration in minutes, and affected circuit segments and SPIDS. Data includes a retrospective lookback for 2018-2022 data (scoped using late-2024 PSPS guidance applied to historical weather conditions), and actual PSPS events for 2023-2024 data (scoped using live guidance at the time of each event, filtered to SCADA-enabled devices). Customer impacts are based on Plan C scoping (the most comprehensive scoping plan, including both distribution and downstream transmission impacts), filtered to Dx-only or Dx-and-Tx events.

The Wildfire Distribution Risk Model (WDRM) V4, provided by the RaDA WDRM team and updated on a three-year cycle. The WDRM is the PSPS Risk Model's source of record for circuit segment geometry.

PG&E Customer Segmentation Data, which identifies the customer service classes and critical customer factors associated with the SPIDs affected by PSPS events.

3.3 Customer-Experienced PSPS Risk Derivation and Example Calculations

The derivation of the full circuit segment mileage-weighted PSPS Risk Model begins with the customer-experienced risk of a single event on a single circuit segment. This is defined as the circuit segment's likelihood of outage (in minutes) for that single event, multiplied by the customer consequence.

Specifically, the PSPS likelihood for a circuit segment during a single event is modeled as the total outage minutes for that event divided by the seven-year PSPS lookback period. In practice, this is implemented by summing all CMI associated with the event and dividing by the

product of the number of SPIDs involved and the seven-year lookback period. This formulation simplifies the coding process while preserving the temporal scaling of the model.

$$PSPS\ Likelihood_{CS,single\ event} = \frac{Outage\ Minutes\ on\ CS}{PSPS\ lookback\ period} = \frac{1}{7years * N_{SPIDS\ on\ CS}} \sum_{SPIDS\ on\ CS} CMI$$

Concurrently, customer-experienced consequence on a single circuit segment (CS) is calculated as the number of SPIDs served by the circuit segment, multiplied by the value of service per CMI ($/CMI) as defined by ICE 2.0 calculator for each SPID's customer class (e.g. residential, small C&I, medium/large C&I), and further adjusted by a weighting factor according to the class of critical customer served at that SPID.

$$Consequence_{CS} = \sum_{SPIDS\ on\ CS} CMI\ cost\ by\ customer\ class * Critical\ customer\ weighting\ factor$$

Thus, the customer-experienced risk on a single circuit segment, for a single event, is the product of the annual likelihood of that event on that circuit segment and the consequence experienced on that circuit segment.

$$Risk_{customer-experienced,CS,single\ event} = PSPS\ Likelihood_{CS,single\ event} \times Consequence_{CS}$$

3.4 By-Count Circuit-Based PSPS Risk Derivation and Example Calculations

If a given circuit segment has multiple upstream segments (possibly including itself) that are affected by a PSPS event, each of these segments is considered an equal *source* of risk, even if the circuit segment itself is the site of the outage. Refactoring the site-based customer risk to a source-based risk model requires attributing the customer-experienced risk equally to all directly affected upstream circuit segments, including the segment itself if directly impacted. This is done by allocating equal proportions of risk to each affected upstream segment. The equations to derive circuit-based risk from customer-experienced risk, based on segment counts, are as follows:

$$Circuit\ Segment - based\ risk\ for\ a\ single\ event, by\ segment\ count:\ R_{CS,e,SB} = \sum_i \frac{1}{N_{i,A}} R_{i,e}\ ;$$

Core spreading may traverse **up to 11 upstream generations** when allocating downstream risk to upstream segments. In cases where a CS/event pair appears in the customer-experienced dataset but does not appear in the upstream ancestor tree, the model applies a

noncore fallback, assigning the event's circuit-segment-level risk directly to that CS without upstream spreading.

When mileage information is required for attribution and multiple mileage measures are available, the model applies a **mileage fallback hierarchy**, using the best available mileage in the following order:

1. Intersection HFTD/HFRA miles
2. Intersection total miles
3. PRIOH HFTD/HFRA miles
4. PRIOH total miles
5. Default of 0 miles

$$Total\ risk\ on\ CS\ for\ all\ events\ in\ lookback\ period = \sum_E R_{CS,E,SB} = \sum_E \sum_i \frac{1}{N_{i,A}} R_{i,e}$$

Where:

$i = set\ of\ all\ downstream\ segments, including\ CS$
$E = set\ of\ all\ events\ that\ directly\ affected\ CS\ during\ lookback\ period$
$R_{CS,e} = Customer\ Experienced\ risk\ for\ single\ CS\ and\ event\ (i.e.\ Likelihood\ x\ Consequence)$
$N_{CS,A} = Number\ of\ ancestors\ of\ CS\ within\ single\ PSPS\ event\ polygon, including\ CS\ itself$

To illustrate circuit-based-based/ risk by circuit count, consider this example calculation of risk from a single PSPS event illustrated in Figure 1.

Figure 1: Example set of PSPS-affected circuit segments

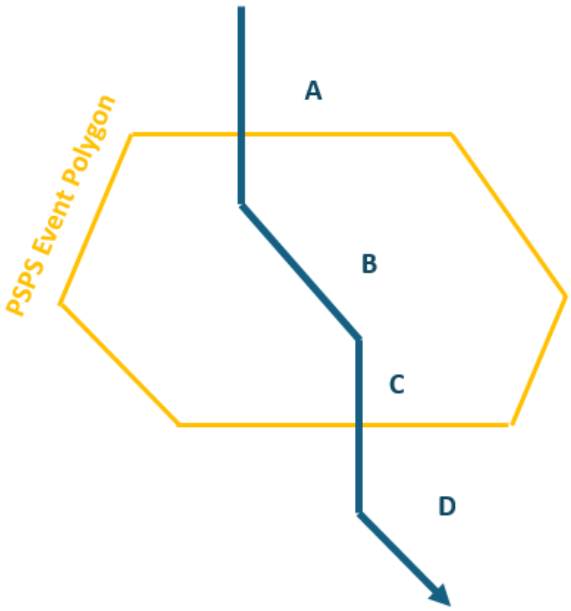

Table 1 Example set of PSPS-affected circuit segments based on Figure 1

CS	$R_{CS,e}$	$N_{CS,A}$	Risk Source Attribution	Circuit-based/ Source-based risk on Segment
A	R_A	1	A has no upstream ancestors in the event. The only source of outage on A is A's own presence in the PSPS event polygon.	$R_A + \frac{1}{2}R_B + \frac{1}{3}R_C + \frac{1}{3}R_D$
B	R_B	2	The source of outage risk on B is equally attributed to A's outage and B's outage within the polygon.	$\frac{1}{2}R_B + \frac{1}{3}R_C + \frac{1}{3}R_D$
C	R_C	3	The source of outage risk on C is equally attributed to A's outage, B's outage, and C's own outage within the polygon.	$\frac{1}{3}R_C + \frac{1}{3}R_D$
D	R_D	3	The source of outage risk on D is equally attributed to outages on A, B, and C. D itself is not a source of outage risk because it lies outside the event polygon.	0

3.5 Circuit-Based Mileage-Weighted Circuit-Based Risk Derivation and Calculations

A simple method for attributing customer-experienced PSPS risk to upstream circuit segments is to distribute each circuit segment's in situ risk equally across all affected segments. However, this introduces bias by treating all circuit segments as equal contributors to risk, when physical geometry also influences the risk each segment carries. Consider a system with an especially long circuit segment, this segment is more vulnerable to inclusion in a PSPS event simply because its length provides a larger exposure surface. From a physical standpoint, circuit segment risk can be modeled as a function of circuit segment length.

When attributing the *in situ* risk of a circuit segment to its upstream source segments, a more accurate approach is to distribute that risk proportionally based on the total length of affected upstream segments, rather than simply by segment count.

To account for the bias introduced by equal attribution, the PSPS Risk Model used in the Outage Risk Model applies a mileage-weighted circuit-based approach. The model's equations are as follows:

$$Circuit-based\ risk\ for\ a\ single\ event, mileage\ weighted:\ R_{CS,e,MW} = \sum_i \frac{M_i}{M_{i,A}} R_{i,e}\ ;$$

$$Total\ risk\ on\ CS\ for\ all\ events\ in\ lookback\ period = \sum_E R_{CS,E,MW} = \sum_E \sum_i \frac{M_i}{M_{i,A}} R_{i,e}$$

Where:

$M_{CS,A}$
$= Miles\ of\ exposed\ ancestor\ CS\ within\ event\ polygon, including\ CS'\ own\ affected\ mileage$

To illustrate mileage-weighted circuit-based risk, consider the following example calculation for attributing circuit-based risk for a single event illustrated in Figure 2.

Figure 2: Example set of PSPS-affected circuit segments, including miles of intersection with the PSPS event polygon

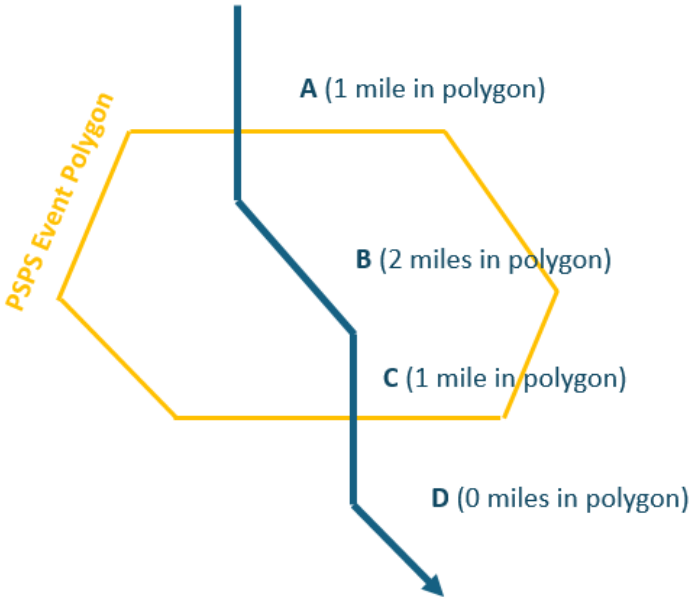

Table 2 Example set of PSPS-affected circuit segments, including miles of intersection with the PSPS event polygon based on Figure 2

CS	$R_{CS,e}$	M_{CS}	$M_{CS,A}$	Risk Source Attribution	Circuit-based/Mileage-Weighted risk on Segment
A	R_A	1	1	A has no upstream ancestors in the event. The only mile of exposed outage source for A is its own mileage within the polygon.	$\frac{1mi}{1mi}R_A + \frac{1mi}{3mi}R_B + \frac{1mi}{4mi}R_C + \frac{1mi}{4mi}R_D$
B	R_B	2	3 (1+2)	The source of outage risk on B is attributed equally across all miles of exposed circuit within the polygon: A's mile of outage and B's two miles of outage within the polygon.	$\frac{2mi}{3mi}R_B + \frac{2mi}{4mi}R_C + \frac{2mi}{4mi}R_D$
C	R_C	1	4 (1+2+1)	The source of outage risk on C is attributed equally across all miles of exposed circuit within the polygon: A's and B's three combined exposed miles, and C's own exposed mile within the polygon.	$\frac{1mi}{4mi}R_C + \frac{1mi}{4mi}R_D$
D	R_D	0	4 (1+2+1)	Segment D itself is not a source of outage risk because its mileage lies outside the event polygon. The source of outage risk on D is attributed equally to the combined four exposed mileage on A, B, and C.	$\frac{0mi}{4mi}R_D$ $(= 0)$

In practice, this mileage-weighted calculation produces the **circuit-segment risk per event**, representing the attributed PSPS risk for each CS x event pair under both the core and noncore pathways. This circuit-segment risk per event serves as the foundational output of the mileage-weighted model and is subsequently used to construct all downstream circuit-level annualized metrics.

3.6 Annual PSPS CMI

The annual PSPS CMI of a given circuit segment is calculated by summing the CMI experienced on that segment over the lookback period, divided by the number of years in that period (i.e., seven years):

$$Annual\ PSPS\ CMI = \frac{1}{7years} \sum_{events,SPIDS\ on\ CS} CMI$$

3.7 Annual PSPS Likelihood

The annual PSPS Likelihood is the annual CMI on a CS divided by its number of SPIDs:

$$Annual\ PSPS\ Likelihood = \frac{1}{7years * N_{SPIDS\ on\ CS}} \sum_{events, SPIDS\ on\ CS} CMI$$

3.8 PSPS Derived Consequence

This circuit-based, mileage-weighted PSPS Risk Model is a summative nonlinear function of a circuit's linear customer-based risk and that of its affected neighboring circuit segments. Due to the interdependence of risk across a series of circuits, it is not possible to define a circuit segment's consequence independently from its likelihood and the customer-experienced risk of its neighbors. In cases where a standalone measure of PSPS circuit segment-based Consequence is needed, use the Derived Consequence, which calculates consequence as a function of risk and known likelihood:

$$Consequence_{derived} = \frac{Risk_{circuit\ segment-based}}{Likelihood}$$

4 Model Usage

4.1 Model Usage

The PSPS Risk Model is applied at the circuit segment level. It is used as a component of the Outage Risk Model used during wildfire season planning and regulatory reporting to assess tradeoffs between wildfire mitigation and customer reliability impacts.

4.2 Shelf Life

The PSPS Risk Model is structured around the Wildfire Mitigation Plan (WMP) reporting cycle and is refreshed in conjunction with new releases of the WDRM. With each Outage Program Risk Model version, the inputs will be updated accordingly with the WDRM and input data.

5 Appendix

5.1 Special Case: PSPS Risk on Circuit Segments with No Customers

Certain circuit segments are present exclusively in the geometric (polygon) dataset and do not appear in any other customer data sources used in the PSPS Risk Model due to having zero customers. This is expected behavior, as the PSPS circuit-based risk is derived from customer-experienced risk; these customer-free circuit segments exhibit CMI across all upstream and downstream paths. Their exclusion from customer-experienced risk models is sound, because there is no customer-experienced risk at the location of those circuit segments.

However, segments without customers can be upstream sources of risk for downstream outages, if the customer-free segment is directly affected by a PSPS event (i.e., its geometry intersects with a PSPS event polygon). I n these cases, customer-free circuit segments are reintroduced to the model so that they can have downstream risk attributed to them, despite their lack of customer-experienced risk and CMI.

These customer-free circuit segments are included in this circuit-based PSPS model as a special case, because outages on these circuits can be the source of significant downstream risk even if they are not the site of customer-experienced service discontinuity.

5.2 PSPS Critical Customer Weighting

The PSPS Outage Risk Model incorporates critical customer weighting by applying severity-based multipliers (1, 2, 5, or 100) to each customer's CMI and VoS. These weighted values are then used to proportionally allocate the total dollarized PSPS risk across the system. Rather than inflating the overall risk, this approach redistributes the existing risk "pie" to give larger shares to customers with higher criticality. This ensures that the model reflects the relative impact of outages on the most vulnerable customer segments, thereby prioritizing mitigation efforts where the consequences are greatest.

The weighting framework was developed in 2022 by subject matter experts and approved by PG&E's Wildfire Risk Governance Steering Committee (WRGSC). It was formally incorporated into the PSPS methodology to support risk prioritization for customers and circuits most impacted by PSPS events. In 2025, internal model comparisons and discussions led to refinement in how customer types were classified. Rather than reducing weights, the trend was to elevate certain customer types, such as TT1 and TT2, to the "Extreme" category, recognizing their role as Public Safety Partners. While some test scenarios explored adjusting weights, these were not adopted in the final methodology. The emphasis remained on reinforcing the importance of critical customers in risk modeling, ensuring that their prioritization was both equitable and operationally sound.

Table 3 PSPS Critical Customer Weighting Overview summarizes the meaning of each weight, listing the specific critical customer types used in the PSPS Outage Risk Model, and provides examples of customer types that fall into each category. These classifications ensure that risk is redistributed, and not inflated, based on customer criticality, allowing the model to prioritize mitigation efforts where the consequences of outages are most severe.

Table 3 PSPS Critical Customer Weighting Overview

Weight	Critical Customer Type	Description & Examples
100	CC1, CE1, TE1, TE2, TT1, TT2	Extremely critical infrastructure, public safety partners or provides emergency services (e.g., critical care facilities, emergency services, telecom hubs, transportation terminals, etc.)
5	Life Support Low Income, Medical Baseline Low Income, Life Support	Medically vulnerable and low-income customers (e.g., life support low income, medical baseline low income, etc.)
2	CC2, CC3, CE2, CE3, EE, PR1, SC1, SC2, SC3, SE1, SE2, SE3, Medical Baseline, Self-Identified Vulnerable, Low Income, AFN (Access and Functional Needs)	Moderately vulnerable groups (e.g., medical baseline, self-identified vulnerable, low income, AFN, etc.)
1	Other	Baseline or regular customers without identified critical attributes

Public Contact With Intact Energized Electric Equipment (PCEEE) Risk White Paper

1. Overview of PCEEE

1.1. Overview

Public Contact with Intact Energized Electric Equipment (PCEEE) is a distinct electric safety risk recognized in PG&E's 2024 Risk Assessment and Mitigation Phase (RAMP) framework. It refers to the risk of serious injury or fatality to members of the public or third-party contractors resulting from interaction with intact, energized electric assets, where the event does not originate from asset failure.[1] Although PCEEE events occur infrequently relative to other operational hazards, they are characterized by high severity outcomes, typically involving electrocution or severe electrical injury.

PCEEE focuses on public exposure to energized infrastructure outside of utility control, emphasizing prevention of unintended or unauthorized contact. This separation supports clearer accountability, more accurate risk modeling, and more effective regulatory oversight. Note that contractor safety and employee safety risks are not included in this risk category.

PCEEE represents a key public safety risk used to calculate Public Safety Benefit in PG&E's Wildfire Benefit Cost Analysis (WBCA) model. See Section 3.1.2 of Attach. B, WP006 (WBCA Whitepaper) for further discussion of PG&E's calculation of Public Safety Benefit.

1.2. Definition and Scope of PCEEE

In the 2024 RAMP, PG&E defines PCEEE as:

The risk of reportable serious injury or fatality to a third-party contractor[2] or member of the public from an interaction with intact PG&E electric assets that did not originate from asset failure.[3]

---

1 Pacific Gas and Electric Company, 2024 Risk Assessment and Mitigation Phase (RAMP) Application, filed May 15, 2024; California Public Utilities Commission, Safety Policy Division, Evaluation Report on PG&E 2024 RAMP Application, November 8, 2024.

2 Third-party refers to a member of the public who is a non-PG&E employee and is not a PG&E contractor (RAMP p.3-2).

3 Pacific Gas and Electric Company, 2024 Risk Assessment and Mitigation Phase (RAMP) Application, filed May 15, 2024; California Public Utilities Commission, Safety Policy Division, Evaluation Report on PG&E 2024 RAMP Application, November 8, 2024.

PG&E's interpretation of this definition relies on several key assumptions:

- **Public-facing risk:** The exposed individual is not a utility employee and is not performing utility-directed work under the utility's safety management system at the time of the event.
- **Intact and energized assets:** The electrical equipment is operating as designed; the initiating event is human interaction rather than equipment malfunction.
- **Severe outcomes:** Events only include CPUC-reportable incidents, meaning fatalities or serious injuries requiring inpatient hospitalization.
- **Exclusion of other risk domains:** Reliability impacts, financial losses, wildfire consequences, and asset failures are addressed in separate risk categories.

2. Where and How PCEEE Events Occur

2.1. Affected Assets and Environments

For purposes of the Electric Undergrounding Plan (EUP), PG&E evaluates PCEEE risk associated with overhead distribution facilities and quantifies the relative risk reduction achieved on a per-mile basis for removed overhead infrastructure.

2.2. Typical Hazard Scenarios and Drivers

RAMP analysis identifies several recurring causal pathways:

- **Third-party working activities** not under utility control, such as construction, farming, or tree trimming near energized overhead lines.
- **Non-working public activity**, including inadvertent contact by individuals engaged in everyday activities.
- **Unauthorized access and vandalism**, including copper theft or intrusion into substations and electrical enclosures.
- **Vehicle or aircraft contact**, such as cranes, tall equipment, or low-flying aircraft striking overhead conductors.

These drivers are predominantly behavioral and situational, rather than environmental or climate-driven, and reflect the inherent hazard of delivering electric service in proximity to public activity.

2.3. Consequences and Public Safety Significance

By definition, PCEEE outcomes involve serious injury or fatality. Electrical contact can result in immediate death, catastrophic burns, neurological damage, or secondary

trauma from falls or fires. Although PCEEE events are low-frequency, each event represents a significant public safety outcome.

In the RAMP framework, PCEEE consequences are evaluated solely through the safety attribute of risk. As required in the Risk-Based Decision-Making Framework (RDF), monetizing the safety attribute requires using a Value of Statistical life (VSL) to convert the estimated fatalities and injuries into an equivalent value expressed in dollars.[4] Reliability, property damage, and financial impacts are excluded to avoid double counting across risk categories.

3. Conclusion

PCEEE (i.e., Public Safety Benefit or Safety Risk Reduction) is a clearly defined, high-consequence public safety risk. While PCEEE's drivers lie largely outside direct utility control, undergrounding presents an opportunity for PG&E to directly mitigate public safety risk and consequence.

Executive Summary

The Risk and Data Analytics (RaDA) team produces a variety of event probability, consequence, and risk models in support of risk mitigation work prioritization and planning. As these models have evolved, the RaDA team has adopted several core algorithms and methodologies for model development and delivery. This document provides an overview of the core RaDA model development tools.

Modeling Algorithms

The RaDA team explores a variety of machine learning algorithms during event model development to determine which algorithm best suits a particular model's objectives. An overview is provided for the three model algorithms currently used by the RaDA team for production event probability models:

- Maximum Entropy (MaxEnt)
- Extreme Gradient Boosting Classification (XGBoost)
- Logistic Regression

Model Performance Metrics

Several performance and feature metrics are considered during model development to determine when predictive model performance is optimal. Overview descriptions and guidance on interpretation of results are provided for the most commonly used metrics.

Model Results Methodologies

The RaDA team probability, consequence, and risk models have been developed to support risk mitigation work prioritization and planning. Frequently, work planning teams need the RaDA model data results to be transformed to match with the particular mitigation program's planning requirements. The RaDA team has developed the following model result transform methodologies in support of mitigation program work planning requirements:

- System Hardening Circuit Segments
- Model Results Aggregation
- Model Results Compositing

Future Plans

New algorithms and methodologies are developed as needed for new model development and to fulfill new user requirements. In response to user requests, there are several new methodologies planned for the aggregation of model results to Isolation Zone, Support Structure, and Regional views.

1 Introduction

The Risk and Data Analytics (RaDA) team produces a variety of event probability, consequence, and risk models in support of risk mitigation work prioritization and planning. The RaDA team has adopted several core algorithms and methodologies for model development and delivery. This document provides an overview of the core RaDA model development tools, including:

- Modeling Algorithms used to match model objectives with machine learning capabilities.
- Model Performance Metrics used to compare and improve model performance.
- Model Results Methodologies for delivering model outputs that support user needs.

1.1 Document Suite

This document is part of the documentation suite for:

- WDRM v4 Documentation
- Wildfire Fire Consequence Model v4 Documentation
- Distribution Network Event Probability Models v4 Documentation

This document will be updated to support additional RaDA team products as they are released, including the Reliability and Public Safety Risk Models currently under development.

This document presents the shared algorithms and methodologies used for development of event probability, consequence, and risk models produced by the RaDA team.

This document provides the lay reader with a broad understanding of the applicability and use of the described algorithms and methodologies. The document does not provide comprehensive detailed mathematical or scientific descriptions.

2 Modeling Algorithms

The RaDA team explores a variety of machine learning algorithms during event model development to determine which algorithm best suits a particular model's objectives. Currently, three model algorithms are used by the RaDA team for production event probability models:

- MaxEnt
- Extreme Gradient Boosting Classification (XGBoost)
- Logistic Regression

The following sections provide overviews of each of the three modeling algorithms and their applicability to RaDA event probability models.

2.1 MaxEnt

Many event probability models use a maximum entropy algorithm, a modeling technique developed by computer scientists at AT&T research and Princeton University for the modeling of ecological prevalence of species. RaDA team event probability models using the maximum entropy approach have been implemented using MaxEnt software.

2.1.1 Overview

MaxEnt probability models are trained on outage locations and their associated environmental and asset attribute data organized onto a set of 100m by 100m pixels that cover PG&E electrical grid. In MaxEnt terminology, event locations are *presence* observations, and the entire set of electrical grid pixels are the model *domain*. To accrue enough data to identify spatial patterns in a set of events, training data typically spans several years. Although it is possible to filter training data by coarse temporal criteria, the typical MaxEnt model is dedicated to spatial, not temporal, patterns. MaxEnt models produce raw relative values that correspond with the relative number of likely grid events by pixel location. Given known event rates, the raw relative event values can be calibrated through a logistic mapping into pixel-based event probabilities.

2.1.2 Constructing MaxEnt Models

MaxEnt delivers an approach for estimating the relative event occurrence rate given a modest number of known event locations. MaxEnt fits a statistical distribution of covariate values for event locations that is consistent with the values at known event locations, but otherwise as similar as possible to the distribution of values found among all modeled locations. The similarity criteria are enforced using a metric called the *relative information entropy* between the distributions of covariate values associated with event locations and all modeled locations. The larger relative information entropy, the more similar are the two distributions. Hence, the overall approach is referred to as a *maximum entropy* estimation of the relative event occurrence rate.

For the distribution event probability models the goal is to use MaxEnt to model the occurrence of ignition and failure/outage events using distribution asset attributes and environmental conditions as model covariates.

The MaxEnt software normalizes its input and target output variables, and therefore produces a normalized output where all predicted probabilities for the domain of a model sum to a value of 1. A scaling parameter is used to calibrate the sum of model domain outputs to match historical fire season event counts.

Maximum entropy as an optimization target has been broadly applied to many types of optimization problems. Therefore, online searches for key words such as “maximum entropy models” may yield results that are not related to the approach implemented by MaxEnt.

2.1.3 Applicability to the Event Probability Models

An important distinction between MaxEnt and many other Machine Learning classification methods is that MaxEnt is a presence-only modeling tool. A presence-only modeling approach trains a model using the locations of known events without requiring ground truth absence data – identification of locations where events cannot occur. Instead, presence-only modeling like MaxEnt compares known event location attributes with the attributes at all other locations.

At first glance, this might seem like an odd choice – whether there is an event or not on the grid is a clear criterion – however, there are several aspects of the wildfire modeling problem that benefit from the choice.

The following aspects of MaxEnt make it useful for spatially oriented contact from object event probability models:

- Contact from object events are typically environmentally driven and rely on spatial data to understand causal paths
- MaxEnt is open-source software with a robust community of users and peer review of its applications
- The MaxEnt software includes support for:
  - Spatial data sets and outputs
  - Feature generation from covariates such as interactions, hinges, thresholds, etc.
  - Regularization that adaptively down weights features that lack or degrade predictive power
  - Support to produce train and test performance metrics

2.1.4 Implementation

The MaxEnt software used for event probability model development is sourced from the Stanford Center for Conservation Biology open source library.

2.1.4.1 Model Data Preparation

There are three types of data that need to be acquired to build an event probability model using MaxEnt:

- Asset attributes for geometry and classifying characteristics such as material, size, age, etc.
- Known event locations used for training, testing, and validating models
- Covariate Values that change over time and space

Some covariates, such as weather and other time-based variables, require derivation, as the data should represent the conditions under which known events have occurred. To support multi-year event datasets, the derivation typically requires statistical extracts of multi-year sequences of weather data. Typical derivations for time-based data such as wind speed and fuel moisture include average values, percentile values, counts of days beyond threshold limits, etc.

All collected data is assigned by its location onto a common set of 100m square pixels that overlay the geometry of the distribution network grid. The grid pixel values are stored into raster datasets for MaxEnt modelling.

2.1.4.2 Iterative Model Process

The process for building an event probability model using MaxEnt is similar to that used for most machine learning (ML) technologies. MaxEnt models are built through an exploratory process managed by a data scientist, iteratively configuring and evaluating candidate models.

A MaxEnt model run configuration specifies options like:

- Source pixel raster datasets
- Attributes and covariates available for modeling events
- Event training, testing, and validation datasets
- Options for model fitting techniques and output scaling
- Options for model evaluation

Once a candidate model has been built from a configuration, MaxEnt produces a variety of reports to assist with model performance evaluation, including:

- Model output evaluation
- Predicted event probabilities
- Model performance metrics for train and test event data
- Model fit performance
- Jackknife charts
- Dropped known events due to insufficient attribute or covariate values

2.2 Extreme Gradient Boosting Classification (XGBoost)

Most distribution equipment asset event probability models use XGBOOST, a boosted decision tree modeling algorithm.

2.2.1 Overview

XGBoost is a powerful machine learning algorithm used for predictive modeling. XGBoost combines multiple weak models, typically decision trees, to create a combined, robust predictive model. The combined model is created using gradient boosting, which iteratively creates new combined model configurations to correct prediction errors produced by previous models.

Key features of XGBoost include:

- Handling of missing values – a common issue for real world data sets.
- Fast and efficient execution on large data sets
- Often provides superior performance against alternative algorithms.

2.2.2 Applicability to the Event Probability Models

The distribution equipment asset event probability models are classification problems and therefore best solved using a classifier modeling algorithm. Using a decision tree-based classifier algorithm provides model feature interpretability through which feature causality can be confirmed by Subject Matter Experts (SMEs). While a single tree model might work well for small data sets, tree-based classifier algorithms tend to overfit larger training data sets like those used for the event probability models, reducing predictive power against novel data sets. As a result, combinations of multiple tree models are typically used for large data sets.

There are two common approaches for combining tree models, bagging and boosting. Bagging algorithms train multiple decision tree models in parallel, while boosting trains models serially. Bagging, or parallel modeling, does not resolve the overfit issues experienced with single tree models. Boosting, which includes a process for pruning out specific tree models, is typically able to minimize model overfit by iteratively training to the residual error produced by its prior tree.

Another advantage for model boosting is that it produces better performance on imbalanced training data sets with very few actual events in comparison to the number of non-events.

There are multiple boosting algorithms available, such as:

- Adaptive boosting (Adaboost)
- Gradient Boosting (GB)
- XGBoost

Adaboost is a basic boosting algorithm and use decision stumps, which are decision trees based on a single feature, to compare performance to determine relative feature importance. Gradient Boosting works similarly to AdaBoost but uses fully trained decision trees rather than stumps. XGBoost follows the same algorithm as Gradient Boosting but uses advanced regularization techniques to suppress weights, prevent overfitting, and enhance its performance against novel data set. Through RaDA team model development research, XGBoost has been selected for building the distribution event probability models.

2.2.3 Implementation

As of document publication, XGBoost 1.7.6 is used for model development.

2.2.3.1 Model Data Preparation

There are three types of data that need to be acquired to build an event probability model using XGBoost:

- Asset attributes for geometry and classifying characteristics such as material, size, age, etc.
- Known event locations used for training, testing, and validating models
- Covariate Values that change over time and space.

Some covariates, such as weather and other time-based variables, require derivation, as the data should represent the conditions under which known events have occurred. To support multi-year event datasets, the derivation typically requires statistical extracts of multi-year sequences of weather data. Typical derivations for time-based data such as wind speed and fuel moisture include average values, percentile values, counts of days beyond threshold limits, etc.

Spatial data, like weather data, is assigned to an asset for XGBoost from a common set of 100m square pixels that overlay the geometry of the distribution network grid.

2.2.3.2 Iterative Model Process

The process for building an event probability model using XGBoost is similar to that used for most ML technologies. XGBoost models are built through an exploratory process managed by a data scientist, iteratively configuring and evaluating candidate models.

A XGBoost model run configuration specifies options like:

- Source datasets
- Attributes and covariates available for modeling events
- Event training, testing, and validation datasets
- Options for model hyperparameters to control regularization and prevent model overfit

Once a candidate model has been built for a configuration, its performance is evaluated using:

- Predicted event probabilities
- Model performance metrics for train and test event data
- Model feature importance
- SHAP plots

2.3 Logistic Regression

2.3.1 Overview

A logistic regression model predicts the probability of discrete outcomes from a set of covariate inputs. A discrete outcome can be any set of ordinal values, such as:

- Yes/No
- True/False
- High/Medium/Low
- Ignition/No Ignition

For any given set of inputs, a logistical regression model will assign a probability for each possible discrete outcome.

Logistic regression models are structured so that the log of the odds of each outcome is a linear combination of the covariate data, which means that once the "log-odds" transform is applied, the model is fit as a standard multiple linear regression. The probability that a binary variable y has a specific outcome given a matrix of all covariate values associated with all observations the binary variable is a logistic function over all covariates with the form:

$$p(y = 1|X) = \frac{1}{1 + e^{-\beta_0 + \sum_{i=1}^{m} \beta_i x_i}}$$

Where:

Variable	Description
P(y=1|X)	Probability that an input event is associated with a modeled outcome
β_i	Covariate correlation coefficients
B_0	Covariate correlation coefficient mid-point
i	Covariate index
m	Number of covariates
X	Covariates matrix
x_i	Covariate vector of values

Logistical regression optimizes a set of logistical functions for each covariate. A generic 1-dimensional logistic function is presented in the *Figure 1*. The y-axis is the probability of the desired binary outcome (True, Yes, 1, etc.) and the x-axis represents the numerical values of one of the input covariates. In this example covariate values below -2 are associated with very low probability outcomes and values above 2 are associated with very high probability outcomes. The function assigns probability value of 0.5 (50/50 odds) for the desired outcome at the midpoint of the curve located at a covariate value of 0.

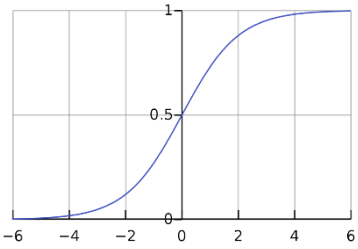

Figure 1 - 1-Dimensional Logistic Function

During the optimization of the logistical regression model, the location of the mid-point 0.5 value along the x-axis can also shifted to the left or right, formulaically expressed as $-\beta_0/\beta_i$. Likewise, the transition steepness of the y-axis from 0.0 to 1.0 can be rescaled during optimization, formulaically expressed as $1/\beta_i$.

2.3.2 Applicability to the Event Probability Models

The RaDA team uses logistical regression modeling to develop the Probability of Ignition given Outage Model, p(i|o), to predict the binary probability of whether an ignition event has occurred as the result of an electrical equipment asset failure or outage event. The model is trained with a data set of historical outage events for which includes a binary indicator of whether an ignition event also occurred. The outage data is combined covariate inputs for weather, fuel, and vegetation conditions as well as the type of failure that initiated the outage to construct the predictive model for probability of ignition given an outage.

2.3.3 Implementation

The DEPM v4 Probability of Ignition given Outage Model was developed using the scikit-learn machine learning framework, written in Python. The details of the modeling process, the model fit, and its predictive performance are discussed in Distribution Network Event Probability Models v4 Documentation.

3 Model Performance Metrics

Several performance and feature metrics are used when evaluating risk and event probability models as fit for purpose. The following sections provide an overview of the most commonly used model performance and feature metrics considered by the RaDA team.

3.1 Model Performance Metrics

Model performance metrics are used to gain insight into how a model performs on data its algorithm hasn't been exposed to during model development. Typically, an out-of-sample test data set is withheld from the data gathered for model training. After fitting a candidate model using a machine learning algorithm, the candidate is exercised to generate model predictions for the test data set. The candidate model predictions are compared against the actual test data set outcomes to produce performance metrics. The performance metrics commonly used by the RaDA team metrics used for evaluating machine learning models are:

- Receiver Operating Characteristic Area Under the Curve (ROC AUC)
- Precision-Recall Curves and Average Precision
- Top 20% Concentration Factor

The distribution event modeling framework produces probability values. The metrics described in the following section support the review of model performance across a full range of probability thresholds for determining event outcomes without the need to compute performance results at a specific probability threshold.

A Confusion Matrix, as shown in *Figure 2*, is used to understand model performance at a particular probability threshold. The Confusion Matrix compares the probabilities predicted by the model to the actual real-world outcome on an out-of-sample test data set. The probability decision threshold is used to determine whether a model probability value indicates a predicted event has occurred or not. Each prediction/test set event pair will fit into one of four Confusion Matrix outcome categories:

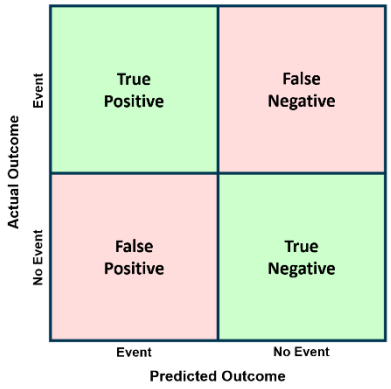

Figure 2 - Confusion Matrix

Table 1 - Confusion Matrix Outcome Categories

True Positive	Event predicted for an actual event
True Negative	No event predicted when there was no actual event
False Positive	Event predicted when no actual event occurred
False Negative	No event predicted when there was an actual event

The Confusion Matrix definitions are the foundation for understanding the model performance metrics described in the following sections.

3.1.1 Receiver Operating Characteristic Area Under the Curve (ROC AUC)

The Receiver Operating Characteristic Area Under the Curve (ROC AUC) measures the tradeoff between capturing True Positives and misclassifying False Positives across the range of thresholds for the predicted probabilities.

Figure 3 shows a sample ROC Curve showing the relationship between the True Positive Rate, also known as recall, and the False Positive Rate, for a given probability decision threshold. For a binary classification such as event / no event, rates are calculated as:

$$TPR_a = {TP_a}/{(TP_a + FN_a)}$$

$$FPR_a = {FP_a}/{(FP_a + TN_a)}$$

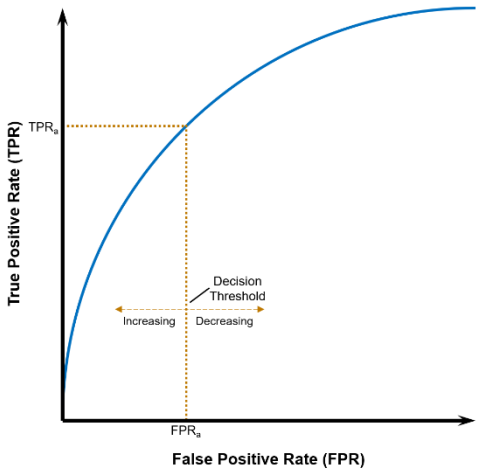

Figure 3 - Example ROC Curve

where:

a	Probability decision threshold
FN	False Negative – predicted no event where event occurred
FP	False Positive – predicted event where no event occurred
FPR	False Positive Rate
TN	True Negative – predicted no event where no event occurred
TP	True Positive – predicted event where event occurred
TPR	True Positive Rate, also know as Recall

Notice that the highest probability threshold occurs where the x- and y-axis meet. This portion of the chart shows the TPR and FPR for the highest probability values since only the highest probability values exceed that threshold.

Figure 4 shows the relationship between ROC and AUC. A ROC that renders as straight diagonal line has an area under the curve, or AUC, of 0.5 and indicates that a model algorithm cannot differentiate between events and non-events across all probability thresholds. In other words, the model performance is no better than random guessing. An ROC curve above the diagonal indicates that a model performs better than random guessing. The steeper the vertical start of the and the flatter the horizontal end of the ROC curve, the higher the AUC and the better a model is at predicting true positives while minimizing false positives for the highest probability thresholds.

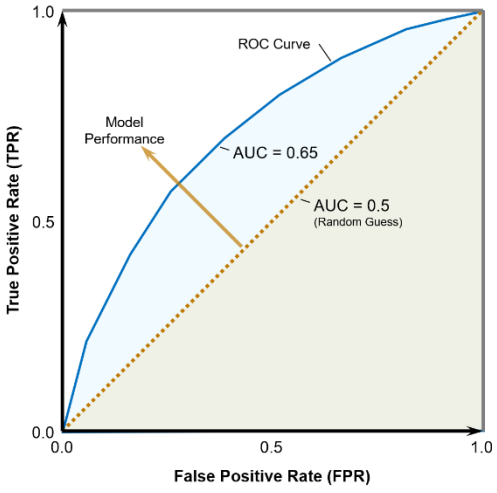

Figure 4 - Example ROC AUC

3.1.2 Precision-Recall Curves and Average Precision

The training data sets for equipment asset event probability models are highly imbalanced, meaning that there are very few event occurrences against a very large number of non-events. Such an imbalance will often lead to an ROC curve that gives too much credit for True Negatives, where an event did not occur and the proposed algorithm predicts no event. True Negatives represent the overwhelming majority of predictions for the event probability models, so it is important to consider the underrepresentation of False Negatives where an event occurred and the proposed algorithm predicts no event. Precision-Recall curves can provide insight into missed event underrepresentation.

Precision-Recall curves measure the tradeoff between converting False Negatives into True Positives at the expense of increasing False Positives. Precision and Recall are calculated across the same range of probability thresholds used to produce the ROC curve (*Figure 3*).

$$Precision_a = {TP_a}/{(TP_a + FP_a)}$$

$$Recall_a = {TP_a}/{(TP_a + FN_a)}$$

where:

a	Probability decision threshold
FN	False Negative – predicted no event where event occurred
FP	False Positive – predicted event where no event occurred
TN	True Negative – predicted no event where no event occurred
TP	True Positive – predicted event where event occurred
Precision	Fraction of True Positives against positive predictions, true or false
Recall	Fraction of True Positives against all positives, also known as True Positive Rate

Figure 5 presents a typical Precision-Recall curve. In this chart, to achieve 20% Recall (also known as True Positive Rate, Precision is reduced to 3.8%. Note that as Precision increases to account for more True Positive results, the Recall declines as the number of False Positive results increases. Therefore, a model that produces the steepest initial downward slope of preferable.

Average precision summarizes the precision-recall curve by calculating the weighted average precision across the entire range of probability prediction thresholds. The weight is the increase in recall from the previous threshold. This value is not interpolated or calculated using the trapezoidal rule with the Area Under the Precision Recall Curve, which can be overly optimistic. It is computed using the Average Precision Score method from scikit-learn, a Python machine-learning library.

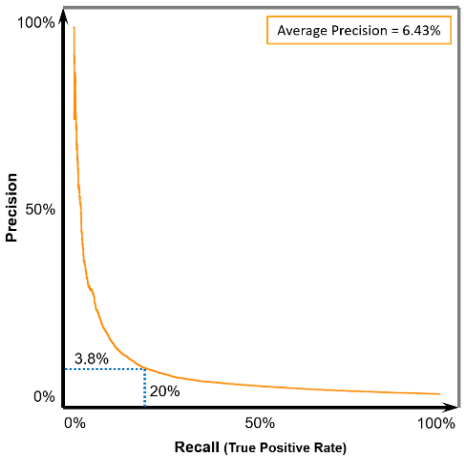

Figure 5 - Example Precision-Recall Curve

3.1.3 20% Concentration Factor

Ultimately, the Distribution Event Probability Models, in conjunction with the Wildfire Consequence Model, are used to prioritize future wildfire mitigation work. Wildfire mitigation work planning tends to consider only the riskiest top 20% of all potential locations on the distribution grid. Therefore, a useful metric for understanding how a model will influence mitigation spend efficiency is to consider a 20% Concentration Factor, which measures how many actual distribution event locations are found in the top 20% of modeled locations when ranked in descending order of predicted event probabilities.

The Concentration Factor is calculated from:

$$Concentration\ Factor = \frac{Events_{Actual}/Events_{Total}}{Locations_{Ranked}/Locations_{Total}}$$

where:

20% Conc. Factor	Model concentration factor for top 20% of ranked locations.
$Events_{Actual}$	Number of events that occurred within the ranked list of locations
$Events_{Total}$	Number of total actual events
$Locations_{Ranked}$	Number of modeled locations considered in order of descending predicted event probability
$Locations_{Total}$	Total number of modeled locations

The 20% Concentration Factor provides insight into the effectiveness of mitigating risk for the highest priority locations or assets. The higher the concentration factor, the more likely that addressing the highest priority locations will truly address locations of significant risk. *Figure 6* provides an example where the top 20% of asset locations by ranked probability include the locations of 71% of all historical events, which equates to a very good concentration factor of 3.55. Therefore, it is likely that mitigation work to the top ranked locations will be very effective in reducing future events. On the other hand, a poor concentration factor closer to 1 would indicate that a model is only slightly better than a coin toss, and that other factors beyond model-ranked locations should be considered before performing mitigation work. Additionally, a model with a poor concentration factor is an obvious candidate for further model development.

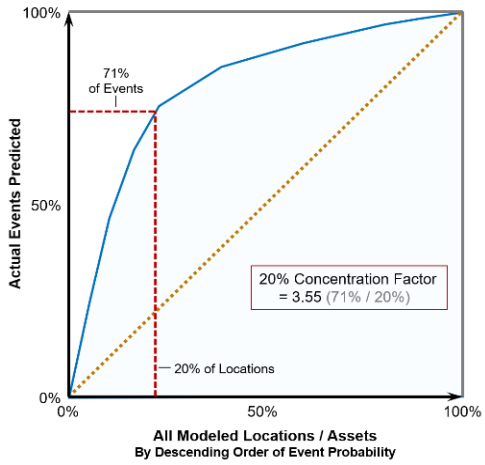

Figure 6 - Example 20% Concentration Factor

3.2 Feature Metrics

Features metrics provide insight into how helpful and influential the inputs are to a model algorithm. The metrics described in the following sections are used to help explain how a machine learning model is influenced by its covariates and hence why it predicts a particular set of probability results.

The most common feature metrics commonly used the RaDA team for evaluating machine learning models are:

- Feature Importance
- SHAP Plots

3.2.1 Feature Importance

A popular metric for evaluating a proposed machine learning model is to examine the relative importance of each input feature to the model output. Two types of feature importance are used for event probability development: permutation importance, use for MaxEnt based models, and total gain feature importance, used for XGBoost based equipment asset models.

Permutation importance for MaxEnt models is determined by sequentially replacing the historical data for each feature with randomly scrambled data and observing the subsequent difference in model performance.

Total gain feature importance is a part of the XGBoost algorithm library. The metric represents the cumulative performance gain across all the tree splits where that feature is used.

Figure 7 shows a typical feature importance chart for a model developed using eight features. The chart displays the features in order of importance to a model from most to least important. Additionally, the length of the bar for a feature represents its relative importance for the model when compared with the other features.

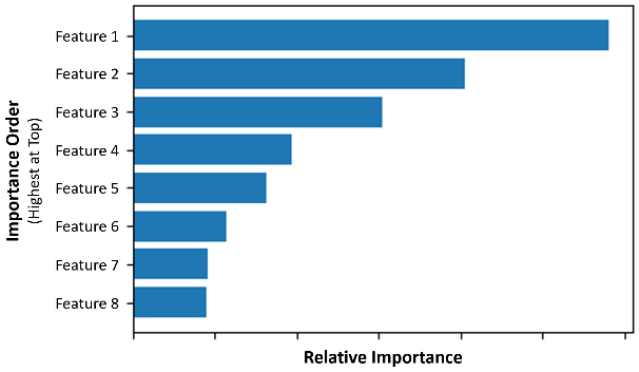

Figure 7 - Example Feature Importance Chart

3.2.2 SHAP Plots

The SHAP plot provides insight into the contribution of each feature to the performance of a model. The plot is based on individual data points in contrary to the total gains feature importance typically used for model feature evaluation. The SHAP plot provides local interpretability by disaggregating by individual data points and shows the contributions of each feature across different observations. In addition, the plot provides intuition about whether a feature has a generally positive or negative correlation with predict values.

SHAP values originate from cooperative game theory. The methodology aims to allocate optimal credit to each feature (emphasis on "cooperative") and make explanations local (so each test case/row can be explained). Not only does each test case have its own SHAP values, but the values across test cases are additive allowing for both individual and group evaluation of the test dataset.

An example of a SHAP plot is shown in *Figure 8*. The SHAP Beeswarm plot uses the local and additive nature of the SHAP values to provide three dimensions of insight to model inputs:

- The plot y-axis is similar to other feature importance bar charts and ranks features from the most important to least important. The feature order is selected according to the mean absolute value of the SHAP values for each feature. This order emphasizes broad impact and can undervalue rare but high magnitude impacts.
- The x-axis shows each SHAP value with a dot for each data set row. The dots aggregate along each feature row to show density, indicating when many rows have similar SHAP values, providing insight to a features SHAP values distribution.
- Color is used to display the relative original value of a feature, with higher values in red and lower values in blue. The color dimension gives insight into whether high or low values are associated with higher probability outcomes, providing a useful check on whether the model algorithm is using feature values as expected.

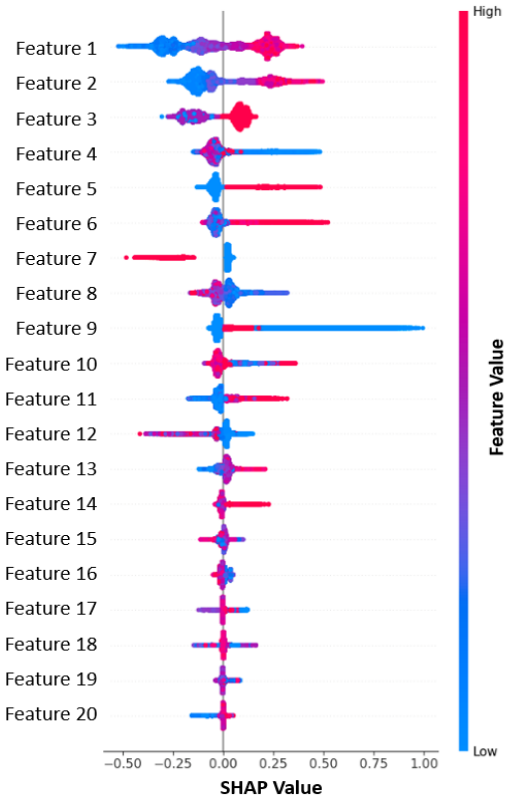

Figure 8 - Example SHAP Plot

4 Model Results Methodologies

The RaDA team probability, consequence, and risk models have been developed to support risk mitigation work prioritization and planning. Frequently, work planning teams need the RaDA model data results to be transformed to match with a particular mitigation program's planning requirements. The RaDA team has developed the following model result transform methodologies in support of mitigation program requirements:

- System Hardening Circuit Segments
- Model Results Aggregation
- Model Results Compositing

The following sections provide overviews of each of the three transform methodologies and their application to RaDA probability, consequence, and risk model results.

4.1 System Hardening Circuit Segments

Circuit Segments are an artificial risk mitigation work planning construct applied to the distribution grid.

A circuit on the distribution grid is the set of electrical grid assets downstream of a substation circuit breaker. However, an electrical circuit is often too large for planning and performing risk mitigation work. Therefore, the System Hardening/Undergrounding wildfire mitigation planning teams have chosen to organize their work by Circuit Segments.

4.1.1 Circuit Segment Definition

A Circuit Segment is the section, or segment, of a circuit and all its connected assets downstream of its closest recloser, or Dynamic Protective Device (DPD). Multiple reclosers on a circuit divide the circuit into various smaller segments such that a fault within any segment will only disrupt power to itself and any downstream segments. An example circuit broken into four Circuit Segments by three DPDs is shown in *Figure 9*.

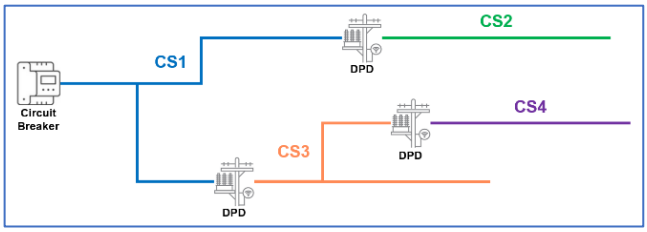

Figure 9 - Circuit Segmentation for Work Planning

There is one significant nuance when defining a work planning Circuit Segment. Some DPDs have switching capabilities that can alter the effective segment configuration during operation. For planning purposes, Circuit Segment configuration is set to match default, or as designed, switch positioning.

4.1.2 Circuit Segment Identification

Circuit Segments are an artificial work planning construct. Each Circuit Segment is identified through logical inspection of the Electrical Distribution GIS (EDGIS) datasets.

4.1.2.1 Circuit Segment Configuration Source Data

The work planning Circuit Segments are determined using grid asset data from three sources:

- Circuit Breaker EDGIS
- DPD EDGIS
- EDGIS Circuit Trace Table

The electrical grid is constantly changing due to maintenance, risk mitigation, and newly installed services. Therefore, it is necessary to use data that is sourced at a specific point in time to minimize configuration mismatches. Snapshot of all three datasets for defining the Circuit Segments are archived by RaDA on the first of each month along with other source datasets necessary for developing risk models. When RaDA begins development on a new set or risk models, all source datasets are synchronized to a common snapshot of data.

4.1.2.2 Protective Device List

As Circuit Segments are an artificial work planning construct, it is necessary to determine from available GIS datasets which electrical assets serve as segment defining protective devices. For System Hardening, this includes Circuit Breakers and DPDs that meet the following criteria:

- Circuit Breakers
  - Substation full circuit breakers
  - Default position configuration, if applicable
  - Parameter: subtypecd = “Source”
  - Parameter: enabled = “True”
- DPDs
  - Default position configuration
  - Parameter: subtypcd = “Recloser”
  - Parameter: status = “In Service”

For Circuit Breakers and DPDs that include configuration switching functionality, additional logic is applied to include only devices with default, as designed, switch settings.

4.1.2.3 Circuit Segment Protected Asset Identification

For every protective device that serves to identify a Circuit Segment, there is a set of electrical assets that the protective device safeguards. The EDGIS Circuit Trace Table is used to cross-reference each Circuit Segment with its protected assets using the global ID of its protective circuit breaker or DPD.

The Trace Table contains millions of relationships that define the distribution grid configuration. The relationships are inspected to determine the global ID of the closest upstream protective device, and hence the containing Circuit Segment, for each electrical asset on the grid.

Unfortunately, due to clerical errors or differences in update frequencies of the EDGIS tables, a very small percentage of assets cannot be mapped to a circuit breaker or DPD in the protective device list. These leftover assets are assigned to an “Unknown” Circuit Segment so that their risk can be accounted for during the modeling process and to facilitate investigation of GIS errors.

4.1.2.4 Circuit Segment Name Assignments

Circuit Segment names are created by combining the circuit name and the protective device operating number for a segment. *Figure 10* provides several examples of Circuit Segment naming for circuit "*El Dorado PH 2101*". The following table illustrates how the circuit name and device operating numbers from *Figure 10* are combined to form unique circuit segment names:

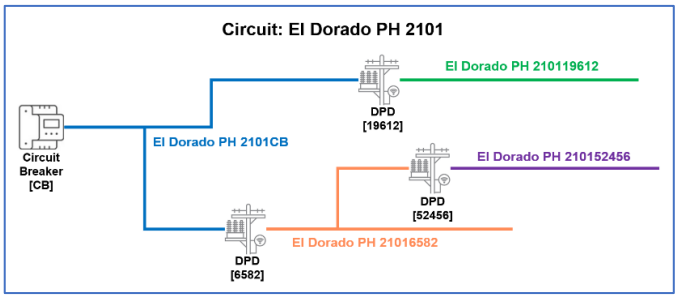

Figure 10 - Circuit Segment Naming

Circuit: El Dorado PH 2101		
Operating Number	**Device Type**	**Circuit Segment Name**
CB	Circuit Breaker	El Dorado PH 2101CB
19612	DPD	El Dorado PH 210119612
6582	DPD	El Dorado PH 21016582
52456	DPD	El Dorado PH 210152456

Table 2 - Example Circuit Segment Names

It is important to remember that Circuit Segment names reflect a fixed point in time. The grid is continuously evolving for reasons such as adding new services, inserting new protective devices for PSPS or EPSS, undergrounding portions of circuits, and replacing or removing circuit sections. Each time the grid configuration changes, one or more Circuit Segments may see a change in name, length, or protected assets. This is the primary reason why the RaDA risk modelling work is always anchored to a set of EDGIS datasets captured at a common date to ensure that mapping of risk results is consistent.

4.1.2.5 Circuit Segment Geometries

Multiple user requirements for the RaDA risk model results are satisfied through analysis of the Circuit Segment geometries. Circuit Segment shape geometries are determined via the cross-referenced protected primary and secondary conductor records from the EDGIS Circuit Trace Table. The geometry of each Circuit Segment protected conductor section is merged to create the total geometry.

The Circuit Segment geometries are required to satisfy two significant user requirements:

- Display risk model results on maps in Foundry as well as other systems such as ArcGIS.
- Determine Circuit Segment lengths in defined areas such as:
  - HFRA
  - HFTD
  - HFTD Tier 2
  - HFTD Tier 3
  - HH Zone 1
  - County
  - Region

Note that location of non-conductor assets, which have point locations rather than geometries, are not merged into the Circuit Segment shape geometry.

4.1.3 Circuit Segment Use for Risk Models

As required by the System Hardening and Undergrounding risk mitigation work planning teams, model results from the Distributions Event Probability Models, the Wildfire Consequence Model, and the Wildfire Distribution Risk Model are aggregated to Circuit Segments. Work planners consider the relative aggregated values for probability of ignition, wildfire consequence, and wildfire risk to prioritize the timing, type, and amount of risk mitigation work that will be performed on high-risk Circuit Segments, especially in high fire risk areas.

Aggregation and compositing of risk model results to Circuit Segments are described in Sections *4.2* and *4.3* of this document.

4.1.4 Circuit Segment Vintage Warning

The GIS datasets used to create a set of distribution Circuit Segments are constantly changing to reflect the current physical state of the grid. While it is possible to continuously update the Circuit Segments as the underlying GIS datasets are updated, this is not useful from a risk modeling perspective. Therefore, any risk model produced by the RaDA team will have a GIS vintage date associated with it. The GIS vintage date for a risk model is recorded as part of its provenance metadata. Users are advised to check and consider the Circuit Segment vintage date when trying to compare or merge risk model results with Circuit Segment based datasets produced outside of the RaDA team.

4.2 Model Results Aggregation

4.2.1 Introduction

RaDA produces both asset and spatial models. Asset models produce results that estimate event probabilities or risk for individual assets at point locations. Spatial, or grid pixel, models, product results that estimate event probabilities or risk within 100m by 100m square pixels that form a grid over the distribution and transmission service territories.

Many end users need to understand model results in a larger context than the direct model outputs. The most used context is Circuit Segment based values. Other contexts that have been requested include county and regional based values. Providing these values requires that the asset and spatial model results be aggregated to the desired context.

4.2.2 Circuit Segment Line Geometry Aggregation

A common user requirement is aggregating model results to a line geometry. While there are several permutations of line geometry possible for the electric grid, the only aggregation currently supported by the RaDA team is the System Hardening Circuit Segment. The aggregated model result for a Circuit Segment is the sum of two components, grid pixel model result values aggregation and asset model result values aggregation.

4.2.2.1 Grid Pixel Aggregation

Many of the RaDA risk models produce results for 100m by 100m grid pixels that overlay our service territory. Pixel model results are aggregated to line geometries like Circuit Segments by summing the model result value for each grid pixel that intersects spatially with the Circuit Segment geometry. *Figure 11* presents a single Circuit Segment that intersects with 14 grid pixels. The aggregated model result value for the Circuit Segment is the simple sum of all intersecting pixel values.

CS Aggregated Pixel Value = A5 + A6 + B1 + … + I7 + J8

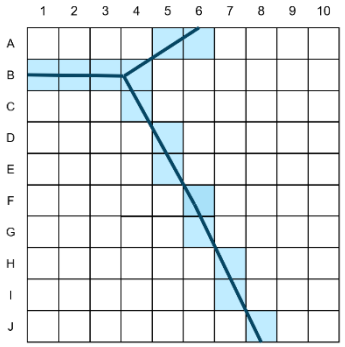

Figure 11 - Single Circuit Segment Pixel Aggregation

Aggregating model results is a bit more complicated when multiple Circuit Segments intersect with one or more shared pixels as shown in *Figure 12*. If the same model result value is summed to both Circuit Segments, then you end up with more summed total Circuit Segment result values then is modeled for the entire grid. In other words, the sum of all Circuit Segment results would be greater than the sum of all pixel results.

The model results aggregation is modified for shared pixels by dividing the model result for each shared pixel by the number of Circuit Segments that intersect it.

Blue CS Aggregated Pixel Value = A5 + … + F6/2 + … + J8

Orange CS Aggregated Pixel Value = G1 + … + F6/2 + … + E10

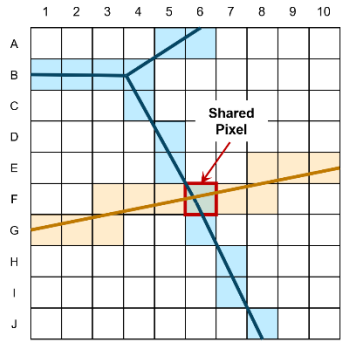

Figure 12 - Multi-Circuit Segment Pixel Aggregation

4.2.2.2 Asset Value Aggregation

Several event probability models produce by RaDA produce results by unique assets. Asset model results are aggregated to line geometries like Circuit Segments through parent-child relationships between assets kept in various system of record databases. Most assets relationships can be established using the EDGIS Circuit Trace Table. Unfortunately, support structure assets are not included in the Circuit Trace Table and their relationship to other assets must be inferred through multiple data sources.

4.2.2.2.1 EDGIS Circuit Trace Table Assets Assignment to Circuit Segments

The EDGIS Circuit Trace Table, which is used to identify and name Circuit Segments, also serves to relationally identify most electrical assets that are associated with a Circuit Segment. This includes:

- Capacitor Banks
- Dynamic Protection Devices (DPDs)
- Fuses
- Switches
- Transformers
- Voltage Regulators

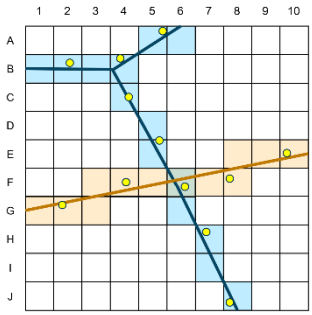

Figure 13 - Circuit Segment Assigned Assets

Unfortunately, Support Structures, which are not energized assets, are not included in the trace table.

Figure 13 presents two Circuit Segments showing both their assigned pixels and assets.

4.2.2.2.2 Support Structure Assignment to Circuit Segments

Support Structures, or poles, require specialized logic to determine their owning Circuit Segment(s). As noted in the prior section, Support Structures are not recorded in the EDGIS Circuit Trace Table as they are not energized assets. Currently, there is no comprehensive single data source that definitively relates Support Structures with Circuit Segments.

Support Structures to Circuit Segment(s) relationships are established through a cascaded search of two datasets in the following order of preference:

1. RaDA's Manual Assignment Dataset
2. Asset Knowledge Management (AKM) Pole to Conductor Dataset

4.2.2.2.2.1 RaDA Manual Assignments

There is a known issue with the AKM Pole to Conductor dataset for assets near electrical stitch points and circuit breakers where there are sometimes too many conductors, and by association circuit segments, assigned to a single support structure. For cases where there are four or more circuit segments linked to a support structure, the RaDA team manually use the EDGIS Web Viewer to review conductor connections and create a custom support structure to circuit segment lookup dataset.

Figure 14 provides an example of the potential need for a manual assignment. The magenta dots represent support structures where there is the potential for as many as four Circuit Segment that could be assigned to each of the poles. The RaDA Manual Assignment Dataset would be used to determine the Circuit Segment and Support Structure relationships.

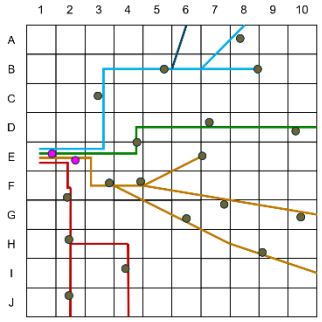

Figure 14 - Circuit Segment Support Structure Assignments

4.2.2.2.2.2 Asset Knowledge Management (AKM) Pole to Conductor Dataset

The AKM team maintains a dataset that is the most reliable source for understanding relationships link between distribution support structures and conductors. The AKM team actively works to maintain and enhance the dataset. The AKM dataset is used for establishing nearly all of the conductor to support structure relationships with the few exceptions originating from the RaDA Manual Assignments dataset described in the prior section. The AKM dataset is snapshotted monthly to support synchronization of model data for development.

4.2.2.2.3 Asset Model Result Aggregation to Support Structures

The following assets have one-to-one relationships with Circuit Segments:

- Capacitor Banks
- Dynamic Protection Devices (DPDs)
- Fuses
- Switches
- Transformers
- Voltage Regulators

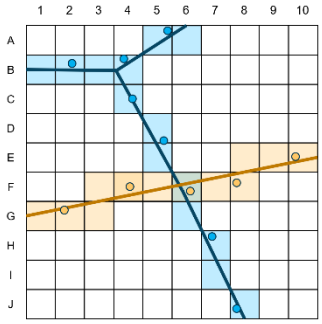

Figure 15 - Direct Asset Risk Aggregation to Circuit Segment

The risk results for these assets list above can be directly attributed to a Circuit Segment. *Figure 15* shows two circuit segments and their directly associated assets for aggregation.

4.2.2.2.4 Support Structure Result Aggregation to Circuit Segments

Support Structure and Primary Conductor risk results are attributed to specific poles. Many poles are associated with multiple Circuit Segment. Pole-based risk results are therefore apportioned equally to associated Circuit Segment depending on the number of connected Circuit Segments. *Figure 16* presents three Circuit Segments with a few shared poles. Their risk results would be assigned and summed as follows:

- Blue CS = 1/3 Red + 1/2 Magenta + 3 Blue
- Green CS = 1/3 Red + 1/2 Magenta + 2 Green
- Brown CS = 1/3 Red + 3 Brown

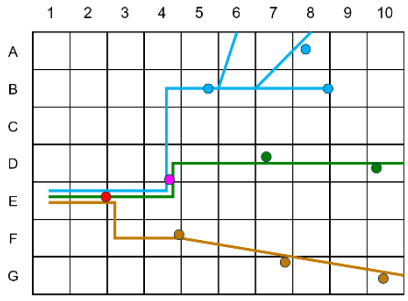

Figure 16 - Pole-based Asset Risk Aggregation to Circuit Segment

4.3 Model Results Compositing

The ultimate purpose for the RaDA risk models is to inform the prioritization of risk mitigation programs. The event probability model risk results can be flexibly composited to provide probability values, risk values, and priority rankings for specific mitigation programs. Using composited results, programs can prioritize mitigation of the highest total risks while using the contributing event probability models to understand the best mediation approach to handle the specific components of risk.

Risk can be composited for any combination of event probability models. Mitigation planners and Subject Matter Experts can focus on the drivers of risk for which they are responsible with confidence that their composited view is relevant to their work planning needs.

4.3.1 Compositing Methodology

An event probability model produces, by asset or pixel, a probability of ignition. Combining a probability of ignition with its consequence produces the wildfire risk. Probability of ignition and risk results can be composited to create total probability of ignition and total risk values. Compositing methodology has evolved as the distribution event probability models have matured and improved.

In producing the WDRM v3, all event probability model results were composited on a pixel basis and equipment asset results were spatially assigned to circuit segments. Unfortunately, a significant number of pixels contain multiple circuit segments. As risk results were attributed to a pixel, v3 compositing lacked a methodology for attributing asset risk at a pixel level proportionally to a specific circuit segment. Therefore, pixel risk would be divided equally between all circuit segments that crossed through a pixel.

For WDRM v4, most of the equipment asset models produce results on an individual asset basis and each asset's relationship with a containing circuit segment is traced through various GIS and SAP data sets. Therefore, equipment asset risk can be attributed directly to a circuit segment, eliminating the shared risk approach necessary for pixel-based results using for v3.

The compositing methodology used by the RaDA team in support of the WDRM is currently a three-step process:

1. Composite pixel model results
2. Composite equipment asset model results
3. Aggregation of pixel and asset composite values

4.3.1.1 Compositing Pixel Model Results

Models that produce pixel results are typically spatially oriented in the context of the risk than threatens the electrical grid network. *Figure 17* depicts a single pixel with multiple potential spatial threats. Individual event probability models for vegetation, animals, and third-party events have produced high, medium, and low risk results, respectively for this particular pixel. Mitigation programs are typically interested in comparing the total risk for the circuit segment that passes through this pixel relative to other circuit segments where work might be performed.

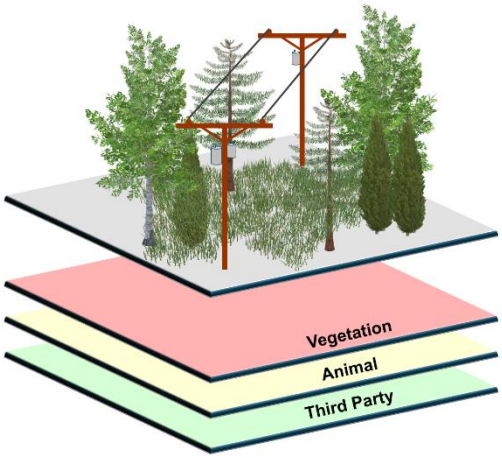

Figure 17 - Pixel Model Layers

Pixel model results are very straightforward to composite, this risk values from each of the contributing pixel models are simply summed to determine the composite risk for a pixel:

$$Composite\ Risk_{pixel} = \sum_{1}^{n} Pixel\ Model\ Risk$$

Figure 18 presents the composited risk value for the example pixel. For this example, a high vegetation risk result and a significant animal risk combine to produce a relatively high overall pixel model risk result for any circuit segment that passes through the pixel.

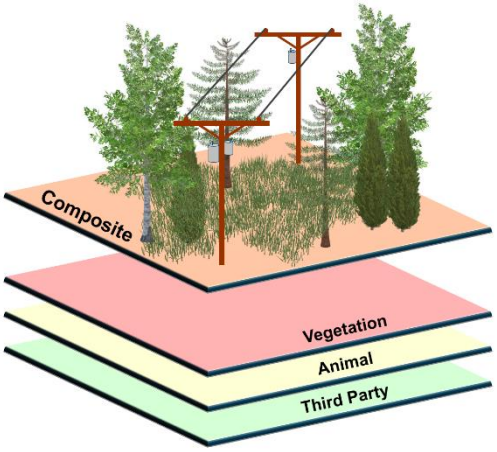

Figure 18 - Composited Pixel Result

4.3.1.2 Compositing Equipment Asset Model Results

Equipment asset models produce risk results that are specific to individual assets. *Figure 19* depicts a very simple example of a circuit segment. Even simplified, there are multiple modeled assets represented, including:

- Two support structures
- Two primary conductor spans
- Three attached transformers

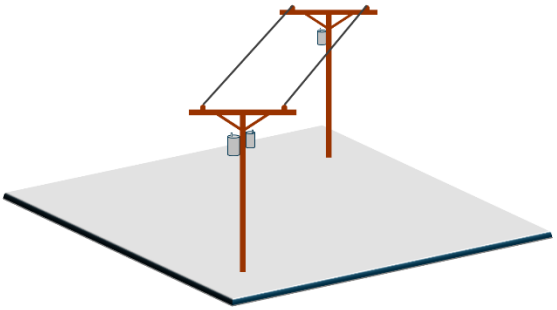

Figure 19 - Simplified Equipment Asset Example

Risk results are generated by the appropriate equipment asset model for each piece of equipment. *Figure 20* displays visually the risk results for each of the individual assets that make up the simple circuit segment. Note that the two support structures, the two conductor spans, and three transformers each have different levels of risk assigned to them.

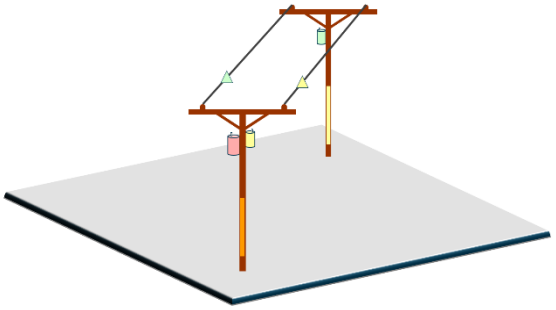

Figure 20 - Individual Equipment Asset Risk Results

The overwhelming majority of equipment assets are pole based. Therefore, equipment assets are composited to the support structure that holds the asset. Conductor spans are a special case in that they are supported by two poles, and hence, their risk must be distributed equally to their support structures.

Figure 21 depicts the compositing of equipment asset risk to the containing support structures. The composite risk indicator at the base of each support structure combines the risk for the pole, the equipment attached to the pole, and half of the conductor risk. Note that any pole with a significant number of attached equipment assets is likely to have a relatively high composite risk simply due to the number of assets.

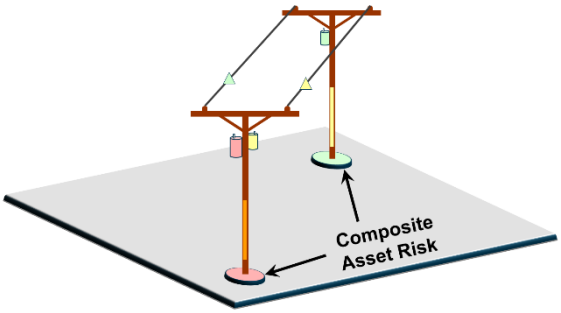

Figure 21 - Composited Asset Risk Example

4.3.1.3 Aggregation of Pixel and Asset Composite Results

Composite pixel and equipment asset results are typically aggregated to the context of circuit segment risk values for mitigation work planning.

Figure 22 depicts a single circuit segment that spans multiple grid pixel areas and has several equipment assets. The aggregated risk value for this segment is the combined sum of three composite pixel risk values and four composite asset risk values.

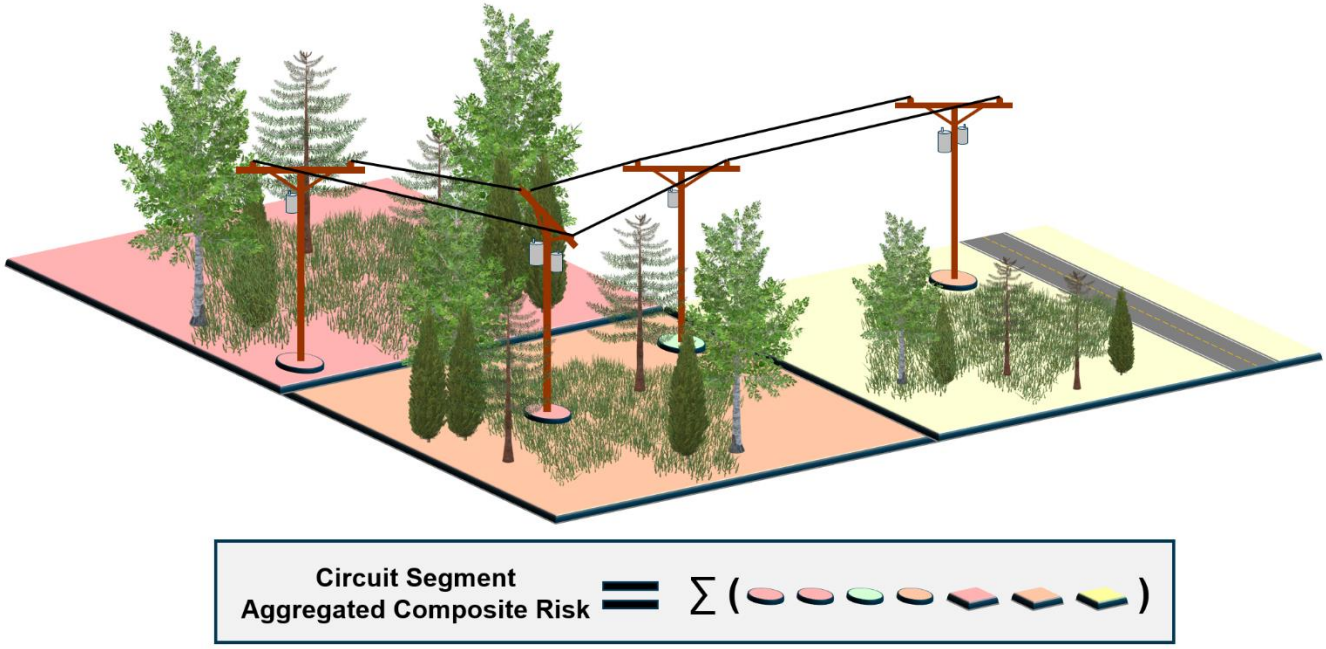

Figure 22 - Single Circuit Segment Aggregated Composite Example

The electrical grid network, however, is more complicated than the example present above. Sometimes, a support structure supports conductors for more than one circuit segment. Another common configuration issue is when multiple circuit segments pass through the same grid pixel. In these cases, some the aggregation must distribute the shared risk. *Figure 23* presents a configuration where two of the grid pixels are spanned by two distinct circuit segments. In this case, while asset risk can be directly attributed to its containing circuit segment, the grid pixel risk must be equally shared by the two segments.

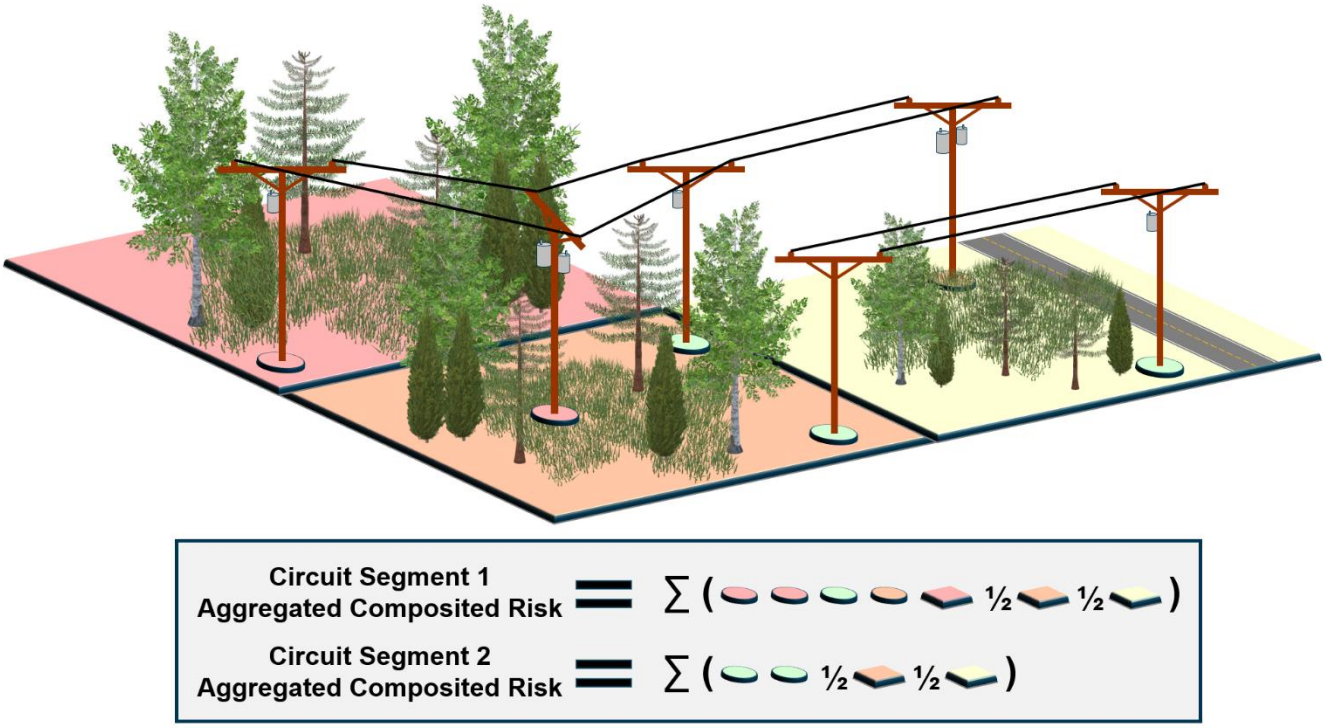

Figure 23 - Multiple Circuit Segment Aggregated Composite Example

4.3.1.4 WDRM v3 and v4 Circuit Segment Composite Aggregation Comparison

The aggregation of composited risk is a major difference between WDRM v3 and v4, and the updated aggregation results in more accurate relative circuit segment risk scores for v4. The single pixel circuit segment configuration provided in *Figure 24* will be used to illustrate the difference between v3 and v4 circuit segment risk values. Note that a set of example risk values have been associated with the icon colors in the figure.

Figure 24 - v3/v4 Circuit Segment Risks Example

For v3, all event probability model risk results were recorded as pixel values. For the sake of brevity, the asset composite results presented in *Figure 24* will be assumed to be pixel level results. For v3, a composited pixel risk value was calculated and distributed equally to the two circuit segments that cross the pixel as shown in *Figure 25*. In the v3 example, each circuit segment was assigned a risk value of 4.5 and the two circuits would have been considered to be of equal priority for mitigation work.

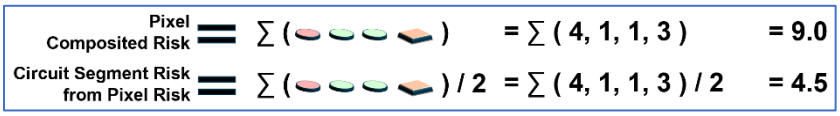

Figure 25 - WDRM v3 Circuit Segment Pixel Risk Assignment

In contrast, for v4 the equipment asset risks are directly assigned to their containing circuit segments and only pixel model risk is shared equally between the two circuit segments. *Figure 26* illustrates that the direct assignment of asset risk results in different circuit segment risk values, and hence, very different priorities for receiving potential mitigation work. This result makes sense, as one segment has an asset with considerably greater wildfire risk than the other.

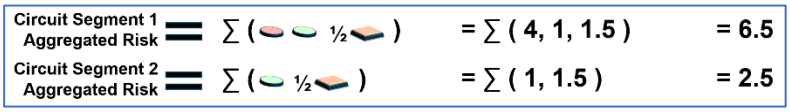

Figure 26 - WDRM v4 Circuit Segment Asset & Pixel Risk Assignment

4.3.2 Mitigation Work Composites

The number of event probability event models has grown with each new version of the WDRM to provide better causal modeling and interpretation of wildfire risk. An All model risk composite, depicted in *Figure 27*, is built for each WDRM version that combines the entire suite all equipment asset and pixel model event probability risk results into a total composite risk result for each circuit segment.

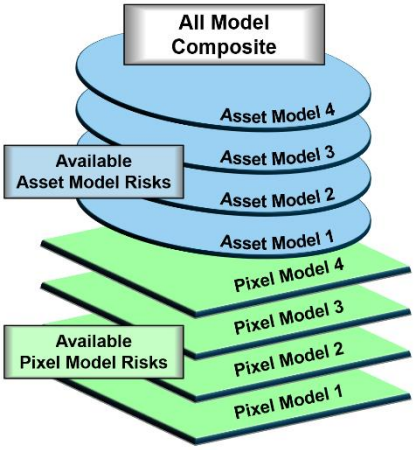

Figure 27 - All Model Composite

The All composite, however, is usually of interest only to the RaDA team for model calibration and quality control. Most mitigation program work planners are interested in only a partial set of event probability model risk results that quantify only the risks that can be addressed by a specific program.

Custom composites are configured so that the total risk for only the applicable event probability models gets considered as part of the work planning and prioritization process. *Figure 28* illustrates how model selection can be used to configure a composite of selected event probability models for a specific work plan. In the example, only a sub-set of the available equipment asset and pixel model risk results are relevant to the mitigation work program.

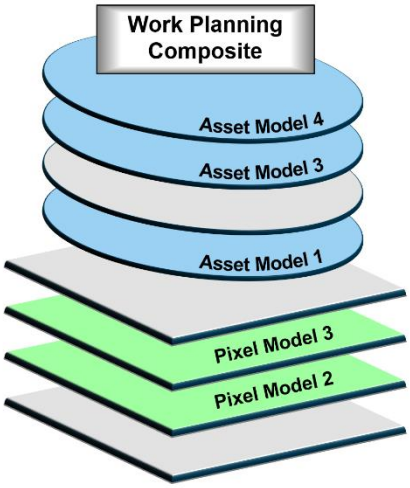

Figure 28 - Mitigation Work Planning Composite

4.3.3 Ignition-Weighted Consequence

The compositing of asset and pixel model results for WDRM v4 revealed that the relationship between aggregated wildfire risk, consequence, and probability of ignition is not straightforward. Simply multiplying an aggregated probability of ignition with an aggregated consequence value will not produce a correct aggregated risk value. To address this issue, it is necessary to back-calculate an aggregated consequence value from aggregations of probability of ignition and wildfire risk. The back-calculated consequence is called the Ignition-Weighted Consequence.

The example circuit segments shown in *Figure 29* will be used to explain how an Ignition-Weighted Consequence value is calculated and why it is necessary for aggregated composites. Note that the only difference in the two circuit segments is the pixel location of the center support structure and its associated assets.

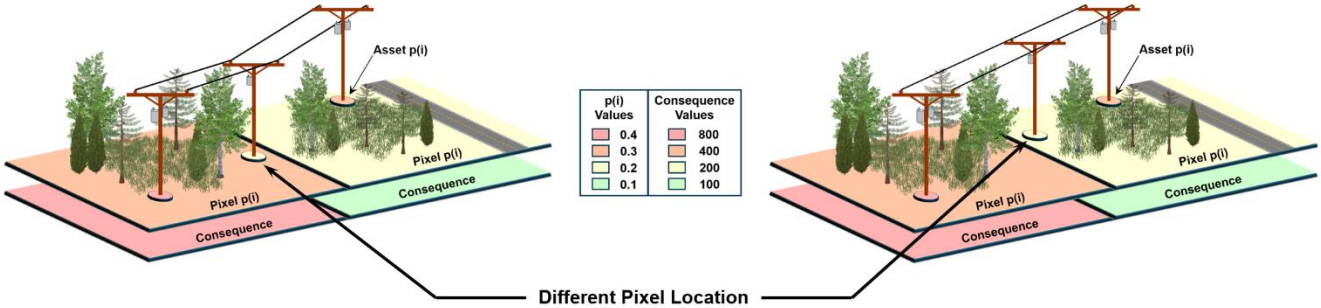

Figure 29 - Ignition-Weighted Consequence Explanation Circuit Segments

The box in the center of the example diagram provides color-coded numeric values for p(i) and wildfire consequence to be used for determining circuit segment risk and ignition-weighted consequence values.

A key understanding for the example is that both circuit segments have identical aggregated p(i) values and the same average consequence value, as shown by the calculations in *Figure 30*. Wildfire risk is defined as a p(i) value multiplied by a consequence value. However, an aggregated composite circuit segment risk value cannot be directly determined by multiplying the aggregated p(i) and the average circuit segment wildfire consequence. Aggregated composite risk must consider the location of the modeled assets to produce the correct aggregated risk value.

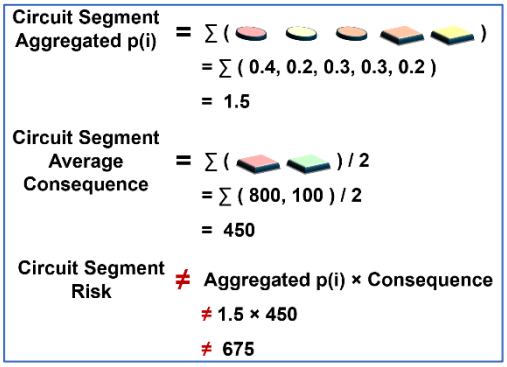

Figure 30 - Incorrect Aggregated Composite Risk Example

Consider the sample circuit segment where the center support structure is located in the left-hand grid pixel (*Figure 31*). For this case the aggregated composite risk would be calculated as shown in *Figure 32*.

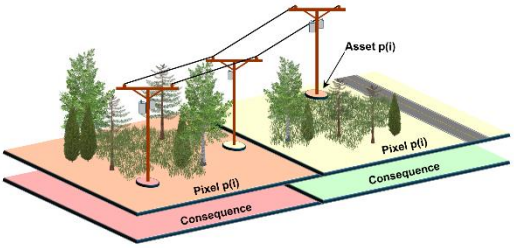

Figure 31- Example Circuit Segment Configuration 1

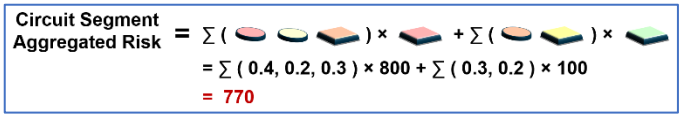

Figure 32- Configuration 1 Aggregated Risk Value

Contrast the results for Configuration 1 with Configuration 2, where the center support structure is located in the right-hand grid pixel (*Figure 33*). The right-hand grid pixel has a much lower consequence value and, as a result, the aggregated composite risk value for the circuit segment will be much lower, as demonstrated in *Figure 34*.

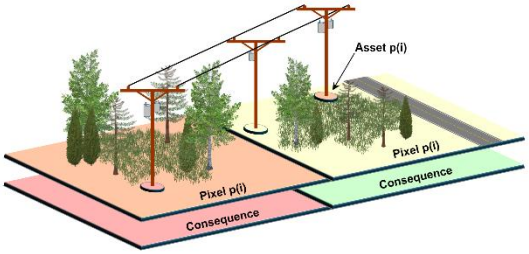

Figure 33 - Example Circuit Segment Configuration 2

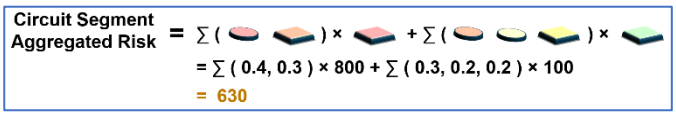

Figure 34 - Configuration 2 Aggregated Risk Value

Note that neither of the aggregated composite risk values determined for the example circuit segment configurations match the risk value calculated from the summed p(i) and average consequence values presented in *Figure 30*.

Since the circuit segment asset configuration against the network grid pixel locations can strongly influence its aggregated composite risk value, then its relative consequence value must also consider the asset locations. This is achieved by dividing the aggregated composite risk value by its summed probability of ignition to yield an ignition-weighted consequence value.

Figure 35 provides the ignition-weighted consequence values for the two example circuit segment configurations. Note that neither of the ignition-weighted consequence values match the average pixel consequence value presented in *Figure 30*.

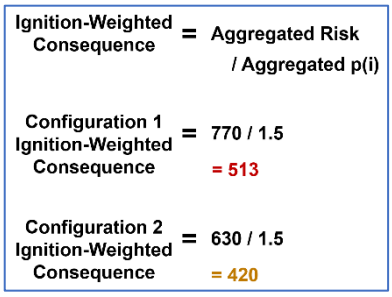

Figure 35 - Configuration 1 and 2 Ignition-Weighted Consequence

5 Future Plans

New algorithms and methodologies are developed as needed for new model development and to fulfill new user requirements. In response to user requests, potential new developments include:

- Isolation Zone aggregation and compositing of event probabilities and risk.
- Support Structure aggregation and compositing of event probabilities and risk.
- Regional aggregation of event probabilities and risk.
- Multi-risk optimization for wildfire, PSPS, reliability, and public safety risks.

WBCA Toy Problem Results

Description *: This workpaper illustrates how the Wildfire Benefit-Cost Analysis (WBCA) tool responds when individual inputs are adjusted, using a simplified "toy problem" to make the tool's mechanics transparent to the reader.*

The "Original" table reflects the baseline output of the WBCA tool, showing the Benefit-Cost Ratio (BCR) calculated from PG&E's standard set of quantified benefits (PSPS, EPSS, wildfire, regular reliability, and public safety risks) and costs (capital and net lifetime O&M). Each subsequent alternative applies a single, isolated change to one input, so the reader can observe, in isolation, how each input influences the resulting BCR. Cells highlighted in blue with a dotted border indicate values that differ from those shown in the Original table.

Together, these side-by-side alternatives demonstrate the directional sensitivity of the BCR to changes in individual benefit and cost components, providing an intuitive walkthrough of the tool's behavior.

	Original	UG Primary

Executive Summary

The Wildfire Consequence (WFC) Model is used by PG&E to estimate the expected outcome of a wildfire initiated by an ignition from an electrical grid asset. The model is based on records of historic wildfires and their outcomes (acres burned, structures lost, and fatalities), which are transformed into comparable units through a Multi-Attribute function (MAVf). The model calculates expected MAV at PG&E grid locations based on the MAV associated with historic wildfires under similar conditions. Consequence values are generally higher at locations that are typically dry, windy, in rough terrain, and have an abundance of burnable fuel.

The WFC supports the Wildfire Distribution Risk Model (WDRM) and the Wildfire Transmission Risk Model (WTRM) missions to quantify and categorize wildfire risk from overhead distribution and transmission network assets. The relative wildfire risk results produced by the WDRM and WTRM inform the PG&E Wildfire Mitigation Plan (WMP) as well as specific mitigation program work plans to help realize the company stand, *"Catastrophic Wildfires Shall Stop."* This document describes the development of the Wildfire Consequence Model version 4 (WFC v4) by the Risk and Data Analytics (RaDA) team and highlights improvements implemented over its predecessor, WFC v3.4.

WFC v4 Improvements

WFC v4 delivered significant improvements to the modeling of wildfire outcomes:

- Improved historical fire data set quality
  - Incorporated additional historical fire data to train the model, which also increased sample size, included smaller fires, and improved estimates through merging multiple source data sets
  - Expanded number of years of fire records
  - Curated fire ignition locations
- Expanded Technosylva fire simulation time from 8 to 24 hours to improve predictive performance for large fires
- Introduced Dry Wind Conditions (DWC) status to help differentiate the highest threat days
- Developed consequence adjustment models for:
  - Public Egress impact
  - Wildfire Suppression impact

WFC v4 Wildfire Consequence Insights

WFC v4 benefited from several improvements. As a result, WFC v4 produces consequence values with improved performance against historical wildfires in PG&E's service territory. WFC v4 also shows less variation in relative consequence values across the system than WFC v3.4. The most critical insight is that WFC v4 has shifted the WDRM v4 System Hardening Composite Risk Buydown Curve, requiring considerably more primary overhead conductor miles to account for 80% of the High Fire Threat District (HFTD) wildfire risk, increasing from 10,000 miles for WDRM v3 to 14,600 miles for WDRM v4.

While there are many contributing factors for the flattened risk buydown curve, a principal cause is WFC v4 outcome changes driven by improved historical fire datasets, introduction of public egress as well as fire suppression impacts derived from Technosylva's Terrain Difficulty Index (TDI), implementation of a revised consequence MAVf, and to a minor extent, 24-hour fire simulations. While new WFC v4 features have improved performance over v3.4, it has also redistributed consequence, and therefore risk, across PG&E's service territory; resulting in a much flatter risk buydown curve.

1 Introduction

The intent of this document is to present the development, performance, and use of the Wildfire Consequence (WFC) model that supports the wildfire risk predictions provided by WDRM v4 and WTRM v2. Source data, modeling approach, and resulting probability predictions are described in detail.

This document describes WFC version 4 (v4) development by the Risk and Data Analytics (RaDA) team and highlights improvements implemented over its predecessor, WFC v3.4. The document seeks to provide the lay reader with a broad understanding of the WFC model. It is not intended to provide comprehensive working-level mathematical or scientific descriptions of all methods used to produce consequence results.

1.1 Wildfire Consequence Model Overview

The WFC v4 estimates the probable outcome of a wildfire initiated by an ignition from an electrical grid asset. The model determines outcomes for number of acres burned, structures destroyed, and fatalities at the location of every grid asset based on weather, vegetation fuels, and terrain conditions. The predicted outcomes are transformed through a Multi-Attribute Value function (MAVf) to calculate a consequence value. Consequence values are generally higher at locations that are typically dry, windy, in rough terrain, and have an abundance of burnable fuel.

An asset location consequence value combined with a probability of an ignition occurring at an asset location produces an estimate of wildfire risk for the asset. Collections of asset risk values provide the wildfire risk mitigation teams with the crucial data needed to prioritize mitigation work plans.

1.2 WFC Role in Distribution and Transmission Wildfire Risk Models

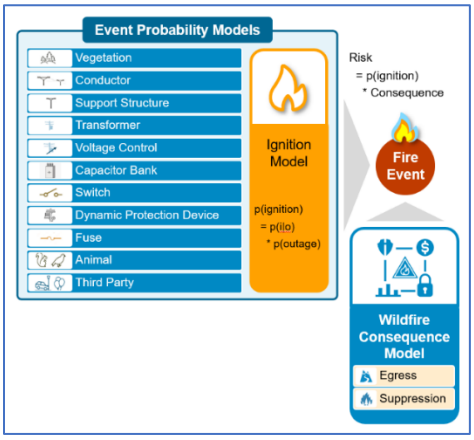

Figure 1 - WDRM Risk Prediction Overview

The Wildfire Distribution Risk Model (WDRM, *Figure 1*) and Wildfire Transmission Risk Model (WTRM, *Figure 2*) are the primary risk models that PG&E uses to provide insights for prioritizing mitigation work to reduce wildfires initiated by the electric grid.

WDRM and WTRM results, along with mitigation program planning tools, are used to develop work plans that systematically reduce wildfire risk, while considering constraints such as budget allocation, human and equipment resource capacity, and regulatory commitments.

The WDRM and WTRM quantify the risk related to PG&E's overhead distribution and transmission equipment assets, which consist of overhead transformers, poles, towers and other support structure parts, lines (conductors), and line-related equipment such as interrupters, switches and fuses. The WDRM and WTRM provide predictions of wildfire risk that occurs during a wildfire season of June 1st through November 30th.

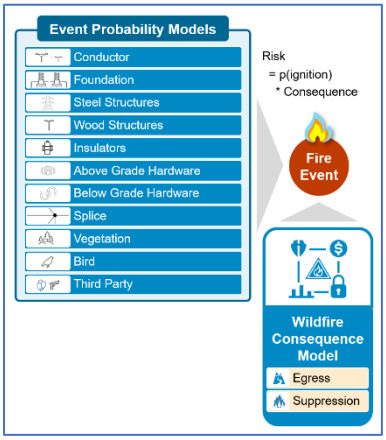

Figure 2 - WTRM Risk Prediction Overview

Wildfire risk is predicted by multiplying two component values. The first component, known as the Likelihood of a Risk Event (LoRE), is the probability of ignition occurring for an asset. The Distribution and Transmission Event Probability Models provide the LoRE values and are described in a separate document. The second component, known as the Consequence of a Risk Event (CoRE), is the predicted outcome of an ignition event at the location of an equipment asset as estimated by the WFC Model described in this document.

1.3 Document Suite

This document is part of the documentation suite for the Wildfire Distribution Risk Model (WDRM) v4:

- WDRM v4 Documentation
- Wildfire Fire Consequence Model v4 Documentation (this document)
- Distribution Network Event Probability Models v4 Documentation
- RaDA Algorithms and Methodologies

2 WFC v4 Highlights and Evolution

The WFC is continuously improved and expanded to incorporate refreshed and new data sources and adopt advancements in wildfire simulation. These improvement efforts are reflected in the evolution of the WFC version releases. Each new version has advanced the science of wildfire consequence modeling in support of PG&E's stand that "*Catastrophic Wildfires Shall Stop*."

2.1 WFC v4 Highlights

WFC v4 features several significant improvements to the modeling of wildfire outcomes:

- Improved historical fire data set quality
  - Incorporated additional historical fire data to train the model; which also increased sample size, included smaller fires, and improved estimates through merging multiple source data sets
  - Expanded number of years of fire records
  - Curated fire ignition locations
- Expanded Technosylva fire simulation time from 8 to 24 hours to improve predictive performance of large fires
- Introduced Dry Wind Conditions (DWC) status to help differentiate the highest threat days
- Developed consequence adjustment models for:
  - Public Egress impact
  - Wildfire Suppression impact

2.2 WFC Version Evolution

Assessment of the potential consequence of a wildfire is a rapidly evolving area of practice where improvements are achieved through the adoption of new data and methods. As a result, the WFC model has evolved and improved over time.

Figure 3 provides an overview of Wildfire Consequence Model evolution. As the understanding of ignition consequences has improved, the formulation of model features developed to produce a consequence value has progressed.

Wildfire Consequence Model Evolution

Feature	v1 (2019)	v2 (2021)	v3.4 (2022)	v4 (2023)
Service Scope	HFTD Tier 2/3	HFTD Tier 2/3	Service Territory	Service Territory

2.3 Legacy WFC Models

The legacy WFC v2 and v3.4 release data are archived and are available for comparison and audit purposes.

2.3.1 WFC v2

WFC v2, developed for WDRM v2, used the results of 8-hr fire simulations provided by Technosylva, Inc. directly for determining consequence values. The simulations modeled the consequence of a fire that was initiated on the worst weather day for a location and accounted for the impacts of by fuel availability and terrain. Simulation outcomes for acres burned, buildings destroyed, and population impact were direct inputs to the MAVf calculation that determined consequence values.

2.3.2 WFC v3 and v3.4

WFC v3 and v3.4, developed for WDRM v3, responded to user feedback to deliver three significant improvements.

- High Fire Threat Area (HFRA)/non-HFRA partitioning.
- Historical fire calibration.
- Predicted Destructive conditions.

HFRA/non-HFRA partitioning was added to support the expansion of WDRM v2, which modeled only assets in HFTD, to WDRM v3, which modeled all service territory assets. The partitioning helped the consequence model differentiate the expected impacts of ignitions that occurred outside of the HFRA.

Historical fire calibration was introduced to adjust the 8-hr fire simulations for final fire outcomes. Large fires last much longer than the 8-hr simulation time and therefore burn more acreage, destroy more buildings, and have a larger public impact than the simulation predicts. The calibration improved consequence accuracy and scale of damage while retaining the spatial and temporal coverage of simulations, enabling the prediction of expected fire damages.

Predicted Destructive conditions were added to aid in the explicit identification of catastrophic or destructive wildfire conditions. This feature was aimed at identifying, with a high degree of recall, the conditions which result in catastrophic or destructive wildfires. The Predicted Destructive conditions status was determined from a combination of PG&E Meteorology's Fire Potential Index and Technosylva's fire simulation data.

2.4 WFC v4 Model Architecture

The WFC v4 architecture was substantially modified from WFC v3.4 to accommodate WMP 2023 commitments for adding public egress and wildfire suppression impacts to the model. The v4 model consists of four components:

- Base Consequence Model
- Wildfire Suppression Impact Model
- Public Egress Impact Model
- Multi-Attribute Value function (MAVf)

The results of the Base Consequence, Wildfire Suppression, and Public Egress models are joined to determine the combined set of model results for acres burned, structures destroyed, and potential fatalities as shown in *Figure 4*. The combined model outcomes become the inputs into the MAVf to determine the final consequence value.

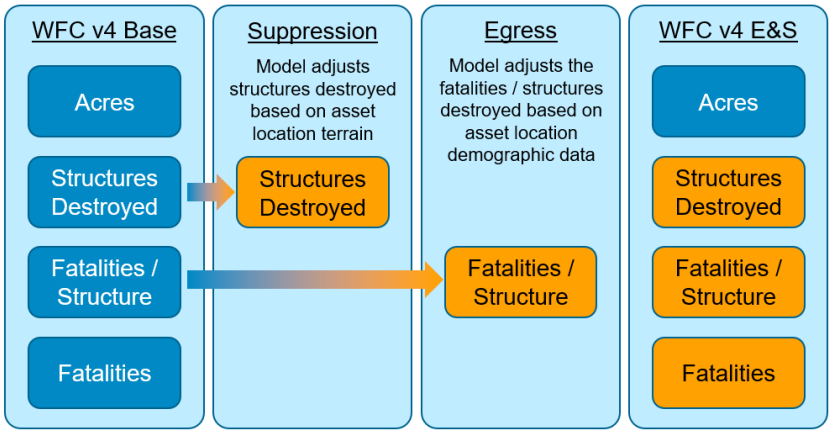

Figure 4 - Wildfire Consequence v4 Model Architecture

2.4.1 WFC Model Process Overview

A high-level process flow of WFC v4 components is depicted in *Figure 5* followed by brief descriptions of each. For an additional illustration of WFC v4 component impact on wildfire consequence, refer to *Appendix 6.4*.

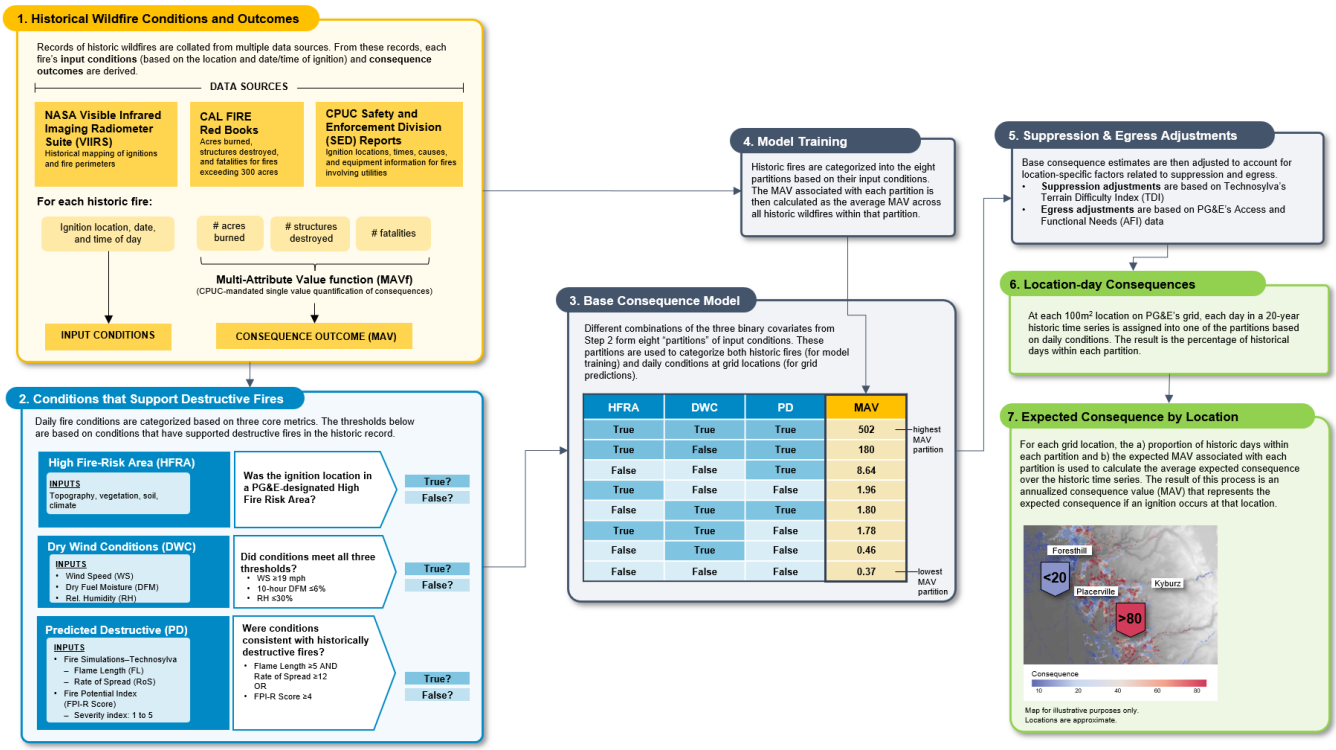

Figure 5 - WFC v4 Model Process Overview

2.4.1.1 Historical Fire Conditions and Outcomes

The WFC v4 is trained using historical wildfire datasets that together provide the times, locations, and consequence outcomes (i.e. acres burned, structures destroyed, and fatalities) for each fire event. Historical wildfire data is sourced from:

- NASA Visible Infrared Imaging Radiometer Suite (VIIRS) satellite data
- CPUC Safety and Enforcement Division (SED) reports
- CAL FIRE Red Books incident data

2.4.1.2 Conditions that Support Destructive Fires

The consequence model associates input conditions (such as weather, fuels, and terrain) with consequence outcomes.

- *High Fire Risk Area (HFRA)* indicates whether the grid location is within the HFRA.
- *Dry Wind Conditions (DWC)* indicates if the weather conditions exceed threshold levels for Wind Speed, Dry Fuel Moisture, and Relative Humidity.
- *Predicted Destructive (PD)* indicates if the Technosylva simulations outputs for Flame Length and Rate of Spread, or if PG&E's operational wildfire Fire Potential Index score, FPI-R, exceed threshold levels.

2.4.1.3 Base Consequence Model

Different combinations of the three destructive fire conditions form a Base Consequence table, representing eight permutations of input conditions, referred to in this document as "*partitions*". These partitions are used to categorize both historic fires for model training and daily conditions at grid locations for model predictions.

2.4.1.4 Model Training

Historic fires are categorized into eight partitions based on their input conditions. The MAV associated with each partition is calculated as the average MAV across all historic wildfires within that partition.

2.4.1.5 Suppression and Egress Adjustments

The Base Consequence Table of historic daily conditions partitions and average expected consequence MAVf values are adjusted for five levels of a Terrain Difficulty Index (TDI) impacting suppression effectiveness, and ten levels of an Access and Functional Needs (AFN) index reflecting public ability to egress.

2.4.1.6 Daily Location Consequence Predictions

Expected consequence for each location on the PG&E grid is calculated based on location-specific daily time series. For a given location, each day is assigned to one of the eight partitions based on the three binary covariates. The result is the percentage of historical days within each partition. At each $100m^2$ pixel location on PG&E's grid, each day in a 20-year historic time series is assigned into one of the partitions based on daily conditions. The result is the percentage of historical days within each partition.

2.4.1.7 Expected Seasonal Location Consequence

For each grid location, the a) proportion of historic days within each partition and b) expected MAV associated with each partition are used to calculate the average expected consequence over the historic time series. The result of this process is an annualized consequence value (MAV) that represents the expected consequence if an ignition occurs at that location.

2.4.2 Multi-Attribute Value function (MAVf)

The MAVf is used in the wildfire consequence model to transform historic wildfire consequences into a single comparable unit for the purposes of model training and prediction. The 2023 Risk Assessment and Mitigation Phase (RAMP) filing implemented a Cost Benefit Approach methodology update to the MAVf that is used for WFC v4. The primary changes to the MAVf are:

- The MAVf output is explicitly $1 million risk-adjusted 2023 dollars per unit of MAVf.
- The Value of Statistical Life (VSL) is $12.5 million, decreased from approximately $100 million.

Assumptions continued from the prior version of MAVf include:

- $1 million per structure destroyed
- Suppression cost is $1,157 per acre
- Serious injury costs are assumed to be 1:1 with fatalities and valued at $3.125 million (0.25 * VSL)
- A non-linear risk adjustment increases the consequences of more extreme events.

The MAVf update shifts consequence values away from loss of life and increases the importance of structures destroyed and acreage burned. The shift is partially mitigated by the correlation of loss of life with the number of structures destroyed. An analysis of the change in MAVf demonstrated minimal change to consequence distribution between WFC v4 and v3.4.

2.5 Performance

WFC v4 benefited from several improvements to the Base Consequence Model as well as the addition of adjustment models for wildfire suppression and public egress. As a result of model developments, WFC v4 produces consequence values that show a significant improvement in predicting wildfire outcomes.

2.5.1 Historical Wildfire Performance Improvement

The changes approved and implemented for WFC v4 were validated through comparison with WFC v3.4, including how proposed changes altered the ability of the model to account for historical fires. In general, the expectation is that the higher consequence areas should account for the majority of historical wildfire outcomes.

Figure 6 presents the relative performance for WFC v4 against WFC v3.4 for the three outcomes that are inputs to the consequence MAVf: acres burned, building destroyed, and fatalities. The graphs plot the fraction of historical fires accounted for against the ranked consequence pixel fraction. The rank consequence pixel fraction is determined by first ranking all consequence pixel values from highest to lowest, then finding the fraction of all pixels accounted for when the pixel that represents the ignition point for a historical wildfire is reached. Model performance improves as the resulting curve moves up and to the left.

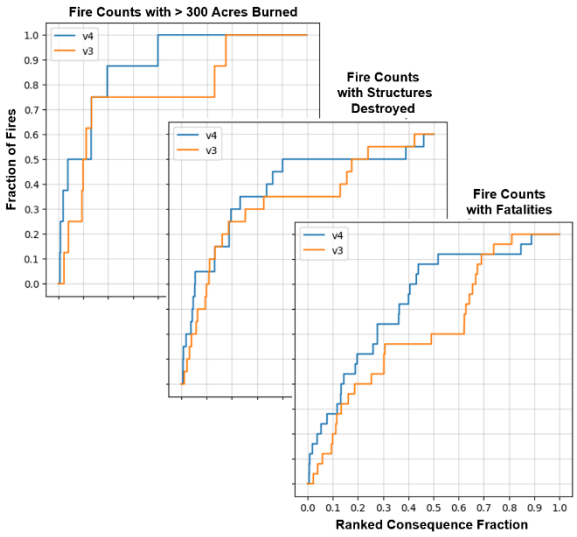

Figure 6 - WFC Historical Wildfire Performance

One way to interpret these graphs is to consider; if an ignition mitigation program were to be implemented in the order of ranked consequence values, how fast would the program reach the ignition points of historical wildfires? The steeper the initial rise of the curve, the quicker the historical ignition points would be mitigated.

WFC v4 outperforms WFC v3.4 for all three historical wildfire outcomes: acres burned, building destroyed, and fatalities. Therefore, the expectation is that WFC v4 will provide improved predictive outcomes for the consequence of ignitions at grid asset locations.

2.5.2 Feature Confusion Matrices

Feature confusion matrices can be used to examine the effectiveness of a feature on predicted outcomes.

Table 1 presents the confusion matrix for fatalities against the Predicted Destructive (PD) conditions feature. The matrix shows that a fatality is 14 times more likely to occur when PD conditions are present.

Table 1 - Fatalities / Predicted Destructive Confusion Matrix

Fatalities	Non-Predicted Destructive		Predicted Destructive		Ratio
One or more	4	0.103%	22	1.474%	14.3:1
None	3877	99.9%	1471	98.5%	0.99:1

Table 2 displays the confusion matrix for fatalities against the Dry Winds Conditions (DWC) feature. The matrix reveals that a fatality is 8 times more likely to occur when DWC is present.

Table 2 - Fatalities / Dry Wind Conditions Confusion Matrix

Fatalities	Non-Dry Wind Conditions		Dry Wind Conditions		Ratio
One or more	12	0.99%	8	8.16%	8.2:1
None	1196	99.0%	90	91.8%	0.93:1

3 Base Consequence Model

The WFC v4 Base Consequence Model is an improved version of the WFC v3.4 that incorporates improved historical fire data and a new Dry Wind Conditions (DWC) feature (see *Table 3* and Section 3.3.2), which further aids differentiating relative consequence during Predicted Destructive (PD) conditions.

Table 3 - WFC Base Consequence Decision Variables

Decision Variable	WFC v3.4	WFC v4
HFRA Membership	✓	✓
Dry Wind Conditions	X	✓
Predicted Destructive	✓	✓

3.1 Key Developments

Several improvements were implemented for modeling the Base Wildfire Consequence Model, explained in further detail in the Training Data and Covariates sections that follow:

- Improved historical fire data set quality
  - Incorporated additional historical fire data to train the model; which also increased sample size, included smaller fires, and improved estimates by merging multiple source data
  - Expanded number of years of fire records
  - Curated fire ignition locations
- Expanded Technosylva simulation time from 8 to 24 hours to improve large fire predictive performance
- Introduced Dry Wind Conditions (DWC) status to help differentiate the highest wildfire threat days

3.2 Training Data

A significant effort was made to improve the quality of the historical fire data set used to train the base consequence model. The training data is assembled from following sources:

- NASA Visible Infrared Imaging Radiometer Suite (VIIRS)
- CPUC Safety and Enforcement Division (SED) reports
- CAL FIRE Red Books

A sample of individual wildfire data is provided in *Appendix 6.2*, *Table 19*.

3.2.1 Visible Infrared Imaging Radiometer Suite (VIIRS)

VIIRS is a sensor package and data product produced by NASA consisting of high-resolution visible infrared images of land, atmosphere, as well as detection of fires, smoke, particles, etc. Data is collected by satellites that pass over the PG&E service territory every 10 to 12 hours; including date, time, location of first detection, fire evolution, and burn area estimate. The satellite raw detections for time, fire intensity, and location are processed by third-party vendor Sonoma Technology Inc. (Sonomatech, STi) through analysis into fire records and organized by unique VIIRS Fire IDs.

VIIRS Fire data provides the following crucial information for fires from 2012 to 2022:

- VIIRS Fire ID, derived from geo-spatial clustering
  (grouping geographic data points based on spatial proximity)
- Initial fire detection
  - Date and time stamp
  - Location
- Fire evolution
  - 10 to 12 hour update frequency
  - Burn area estimate

Satellite monitoring is limited by the need for a fire to endure and reach a certain size for a fire to be detected. Most fires larger than 300 acres persist long enough to be seen from space and therefore appear in the VIIRS data set. Smaller fires, particularly those of less than 10 acres, often do not get added to the VIIRS data set because they are frequently out and cold before a satellite passes over.

Another issue with satellite monitoring is that an initial fire detection often occurs several hours after an ignition due to the satellite pass frequency. Therefore, a fire can already be rather large at the time of detection, and the ignition point can be ambiguous in VIIRS. Furthermore, wind can blur the fire footprint, resulting in fire detection well away from the actual combustion area.

3.2.2 CPUC Safety and Enforcement Division (SED)

CPUC Safety and Enforcement Division (SED) investigates major fires that are suspected to involve an Investor-Owned Utility (IOU). The SED produces detailed reports on the ignition locations, times, causes, involved electrical equipment, Supervisory Control and Data Acquisition (SCADA) information (i.e., real-time data including voltage, current, watts, switch status), etc., pertinent to determining fire causes. The reports are compiled using information gathered from SED, IOU, and fire team sources.

3.2.3 CAL FIRE Red Books

CAL FIRE Red Books are annual publications on the outcomes of major fires that burned more than 300 acres. The recorded fire outcomes of acres burned, structures destroyed, and fatalities are used to calibrate the WFC with historical results. Unfortunately, using the CAL FIRE Red Book outcomes is a mostly manual process. Fire IDs must be joined with the Integrated Reporting of Wildfire Information (IRWIN) database to extract ignition locations that can be matched against VIIRS data.

3.2.4 Lightning Fires

During WFC development, analysis showed that the expansion of the historical fire training data set included several lightning-initiated fires that skewed the consequence model results away from conditions that are expected to have high consequence values. The skewed results were caused by several high impact fires that occurred in a HFRA during non-Predicted Destructive (PD) and non-Dry Wind Conditions (DWC) days ignited by lightning strikes[1]. Lightning fires often occur in highly remote locations[2] and/or during relatively benign conditions[3] . In these cases, the ultimate consequence, especially in terms of acres burned, is larger than would be expected for an electrical asset-initiated fire[2]. As a result, lightning fires in HFRA on non-Predicted Destructive (PD) and non-Dry Wind Conditions (DWC) days have been excluded from the historical fire training data set.

[1] Human-triggered California wildfires more severe than natural blazes (*Van Wyk Joel), 2026.*

[2] Extratropical forests increasingly at risk due to lightning fires (Veraverbeke et al.), November 9, 2023.

[3] Lightning-ignited wildfires in the western United States: Ignition precipitation and associated environmental conditions (Kalashnikov et al.), August 14, 2023.

3.3 Model Covariates

3.3.1 Technosylva Wildfire Simulations

Technosylva is a wildfire simulation and analysis company that produces products marketed to fire fighters, the insurance industry, and utilities. The PG&E Meteorology team contracts with Technosylva to provide FireSight (formerly WRRM) fire spread simulations under different fuel and weather conditions at historical fire and electrical asset locations throughout the distribution and transmission grid networks to determine destructive conditions. Two updates were requested for Technosylva wildfire simulation data for WFC v4:

- Localized simulation of historical fires
- 24-hour simulation times

Technosylva wildfire simulations were explicitly requested at the locations for historical fires from the VIIRS dataset for WFC v4. In contrast, WFC v3.4 used a wildfire simulation from the nearest electrical asset within an 8 km radius to any given VIIRS fire ignition location. In many cases, the fuel and weather conditions at the nearest asset were significantly different from conditions at the wildfire ignition point, leading to modeling issues for predicting consequence at asset locations. In some cases, for very remote wildfire ignition points, there would be no electrical assets within the 8 km search radius, and therefore the VIIRS fire would not be included in the training set. Sending explicit location and conditions data for historical wildfires to Technosylva for simulation both improved the quality and quantity of returned wildfire simulations for the WFC v4 training data set.

Reviews of WFC v3.4 raised concerns over the 8-hr time duration used for the Technosylva wildfire simulations. Most catastrophic fires last for days and sometimes weeks and at issue was whether or not a longer simulation time would help differentiate when a wildfire was likely to become catastrophic. Technosylva was tasked to produce both 8-hr and 24-hr wildfire simulations in support of WFC v4 development.

To analyze the impact of 8-hr vs 24-hr simulations, each historic fire from the fire training data set was paired with its 8-hr and 24-hr simulation results. The initial Pearson R correlation results for the 8-hr and 24-hr simulations were very low, only 0.0637 and 0.0795, respectively. Applying a logarithmic transform to the data improved the correlation results for the 8-hr and 24-hr simulations to 0.198 and 0.208, respectively. *Figure 7* presents a log-log plot of the historical fire simulation pairs with 8-hr results in blue (●) and 24-hr results in orange (●). Note that many of the 24-hr simulation pairs are shifted to a larger simulated burn size.

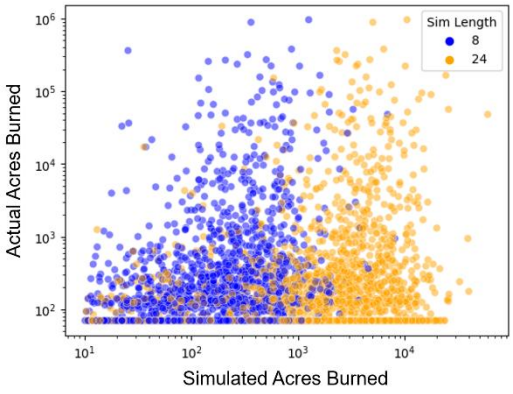

Figure 7 - 8-hr & 24-hr Fire Simulations (log-log scale)

The difference in 8-hr and 24-hr performance becomes clearer when the data pairs are binned as presented in *Figure 8*. The binned plot confirms a general shift to larger simulated burn size for 24-hr simulations. Importantly, the plot reveals a much smoother relationship between simulated and actual burn size for 24-hr simulations.

In the end, 24-hr wildfire simulations were chosen to develop the WFC v4 model due to the smoother relationship between simulated and actual burn sizes. However, the overall impact to relative consequence values was minimal.

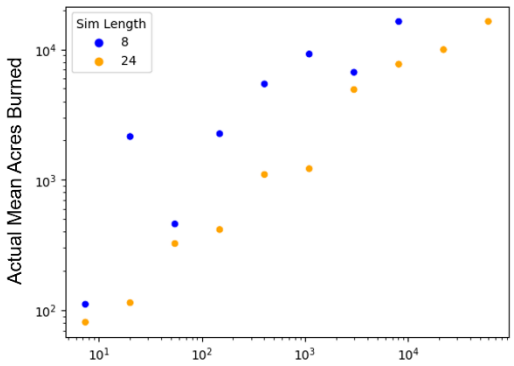

Figure 8 - Binned 8-hr & 24-hr Fire simulations (log-log scale)

3.3.2 Dry Wind Conditions (DWC)

A Dry Wind Conditions status was developed for the consequence modeling in response to both internal and external reviews of WFC 3.4 recommending the inclusion of Red Flag Warnings (RFW) issued by the National Weather Service (NWS). RFW warnings are issued by the NWS when there are weather conditions that would intensify fires.

The PG&E Enterprise Risk Management (ERM) team shared their research findings with the RaDA team that supported that destructive and catastrophic fires occurred primarily during RFW. A RaDA team analysis uncovered two significant issues with using RFW as a consequence model covariate:

- RFWs are issued for Fire Weather Zones (*Figure 9*) that are defined by an arbitrary mixture of watershed areas, ridgelines, and jurisdictional boundaries such as county lines.
- RFW declaration criteria is not consistent across each Fire Weather Zone and create geospatial discontinuities in RFW data – an RFW declared for one zone while RFW is not declared for a second zone with identical weather conditions. *Appendix 6.1* provides specific RFW criteria for Fire Weather Zones.

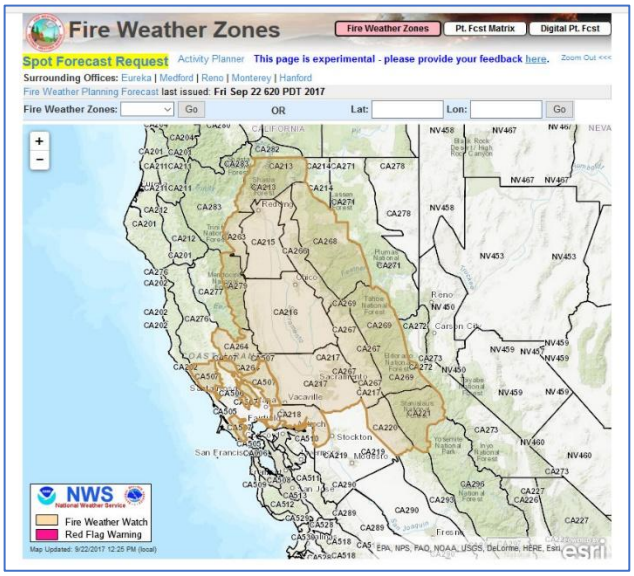

Figure 9 - NWS Fire Weather Zones

RFW inconsistencies cause problems when trying to fit it as a model covariate as the result may be a prediction based on RFW definition rather than actual local conditions. To avoid the RFW inconsistency issue, the RaDA team developed DWC as an internal status covariate. DWC is simply a variation of RFW limit criteria applied evenly across the service territory as shown in *Table 4* The limit criteria for wind speed and relative humidity were aligned with similar criteria used for PG&E Meteorology's Fire Potential Index R-score.

Table 4 - Dry Wind Conditions Criteria

Measurement (daily average)	Limit
Wind Speed	>= 19 mph
10-hr Dry Fuel Moisture	<= 6%
Relative Humidity	<= 30%

3.3.3 Predicted Destructive (PD)

The Predicted Destructive (PD) conditions status, developed for WFC v3, combines results from PG&E Meteorology's Fire Potential Index (FPI) and Technosylva's fire simulation results for flame length (FL), the distance from flame tip to the middle of fire base, and rate of spread (RoS) indices. Wildfire conditions are assessed by assigning odds of destructive fire outcomes, expressed as an FPI-R score ranging from 1 to 5, capturing fire severity as a function of FL and RoS. If simulated or predicted outcomes are consistent with those given to past destructive fires, the day/location is assigned a Predicted Destructive (PD) status.. *Table 5* shows the criteria for determining the Predicted Destructive (PD) status of a location for any day in the wildfire season.

Table 5 - Predicted Destructive Criteria

Measurement (daily value)	Limit
FPI-R	>= 4
OR	
[Flame Length	>= 5
AND	
Rate of Spread	>= 12**]**

3.3.3.1 Fire Potential Index R-score (FPI-R)

The Fire Potential Index R-score (FPI-R), developed and maintained by the PG&E Meteorology Team, is a critical tool for determining the probability of a fire becoming large or catastrophic, in order to drive operational decisions for reducing utility-caused fires risk such as Public Safety Power Shutoff (PSPS) events and grid protection settings. The FPI is modeled at a 2 km by 2 km spatial resolution, providing data at hourly intervals for operational uses and daily intervals for planning uses. Daily interval FPI-R data is used for consequence model development. The FPI-R methodology did not implement any significant updates between WFC v3.4 and WFC v4. *Table 6* provides FPI-R Score rating descriptions.

Table 6 - FPI-R Score Ratings

State	Rating	Description
Low	R1	Very little or no fire danger
Moderate	R2	Moderate fire danger
High	R3	Fire danger is so high that care must be taken using fire-starting equipment. Local conditions may limit the use of machinery and equipment to certain hours of the day.
Very High	R4	Fire danger is critical. Using equipment and open flames is limited to specific areas and times.
Extreme	R5	Open flames not allowed in certain areas.
Public Safety Power Shutoff (PSPS)	R5+	The greatest level of fire danger where rapidly moving, catastrophic wildfires are possible. This is typically when fire danger is R5 "plus" and there are high-risk weather triggers.

3.4 Base Consequence Table Construction

The Base Consequence Model partition table associates input conditions with consequence outcomes derived from historic wildfires.

- *High Fire Risk Area (HFRA)* indicates whether the grid location is within the HFRA.
- *Dry Wind Conditions (DWC)* indicates if the weather conditions exceed threshold levels for Wind Speed, Dry Fuel Moisture, and Relative Humidity.
- *Predicted Destructive (PD)* indicates if the Technosylva simulations outputs for Flame Length and Rate of Spread, or if PG&E's operational wildfire Fire Potential Index score, FPI-R, exceed threshold levels.

The three core criteria are used as stratifying variables to create eight distinct "partitions" of input conditions. The eight condition partitions are referred to using a descriptive shorthand of their respective true or false statuses in the order of HFRA, Dry Wind Conditions (DWC), and Predicted Destructive (PD). Hence, the consequence partition for a location in a HFRA, on a day not under Dry Wind Conditions (DWC), but on a Predicted Destructive (PD) day is referred to as a "T/F/T" partition wildfire.

Each historic wildfire in the training dataset is assigned into one of the eight partitions based on the input conditions associated with the location/day of ignition. For each historic wildfire, consequence is calculated based on acres burned, structures, destroyed, and fatalities using the MAVf. The expected consequence associated with each partition is then calculated as the average MAV for the historic fires that were assigned into that partition. The MAV for each partition is then used to calculate expected consequence on the grid (see *Section 3.5* below). By partitioning locations based on consequence estimates, mitigation work can focus on the highest fire spread consequence areas to achieve the greatest risk reduction.

A sample of individual wildfire data is provided in *Appendix 6.2*, *Table 19*. The consequence values of all member wildfires are summed and averaged to determine the consequence value for a partition. The WFC v4 base consequence partition values are provided in *Table 7*.

Table 7 - Base Consequence Table

HFRA	Dry Wind Conditions	Predicted Destructive	MAVf
True	True	True	502
True	True	False	1.78
True	False	True	180
True	False	False	1.96
False	True	True	1.80
False	True	False	0.46
False	False	True	8.64
False	False	False	0.37

3.5 Base Consequence Partition Table Application

The Base Consequence Partition Table assigns average consequence values for grid asset locations for every fire season day from 2012 through 2022. Each wildfire season is defined as the 183 days from June 1st through November 30th. With 11 wildfire seasons, daily consequence values can be assigned to a total of 2,013 days. In other words, the model assumes that for a given location, the expected consequence for each day in the time series is the average consequence for all historic wildfires that had the same input conditions as the prediction location/day. These individual daily predictions are then averaged across the entire time series to produce base consequence value for a given grid location.

Consider the following specific example of the process described above. Referring to *Table 8*, across a full set of wildfire season days, an electric grid pixel located in an HFRA ("T"), with no Dry Wind Conditions (DWC) ("F"), and no Predicted Destructive (PD) conditions ("F"), is categorized into a "T/F/F" partition and assigned an average MAVf consequence value of 1.96 (meaning that the average MAV of historic wildfires in the T/F/F partition is 1.96). This is considered lower risk than a grid pixel located in an HFRA ("T"), with Dry Wind Conditions (DWC) ("T") and Predicted Destructive (PD) conditions ("T") which is categorized as "T/T/T" partition with an average MAVf consequence value of 502. For each grid pixel historic conditions partition, MAVf consequence is multiplied by the number of wildfire season days to produce MAVf sums. Then, each grid pixel conditions partition MAVf sum is summed to calculate a total MAVf sum (127,554), then divided by the total number of wildfire season days (2,013) to produce a total average MAVf consequence = 63.4 for the wildfire season. Note that while the very different MAVs associated with the individual partitions would appear to suggest consequence model outputs are very polarized – these are applied at the level of daily predictions. For each location, individual days will be assigned to the partitions at rates that vary by location. The subsequent step of annualizing/averaging the daily consequence smooths the final results and results in a range of average MAVs beyond just those visible in the partition table.

Table 8 - Asset Location Base Consequence Value Example

HFRA	Dry Wind Conditions	Predicted Destructive	MAVf	Wildfire Season Days	MAVf Sum
True	True	True	502	50	25,100
True	True	False	1.78	150	979
True	False	True	180	550	99,000
True	False	False	1.96	1,263	2,475
Total				**2,013**	**127,554**
Average			**63.4**		

4 Adjusted Consequence

In compliance with WMP 2023 commitments, PG&E investigated the potential impacts of suppression efforts and public egress on wildfire consequence predictions. Subsequently, consequence impact models were developed for both Wildfire Suppression and Public Egress.

The Wildfire Suppression and Public Egress Models impact consequence by adjusting the number of structures destroyed and fatality rates determined by the Base Consequence Model, and changing the input values used by the consequence MAVf calculation. In this context, the Base Consequence Model (and its outputs) should not be interpreted to estimate consequences without suppression or egress. Instead, they should be interpreted to estimate consequences without considering spatial differences in the relative ease of carrying out suppression or egress. The Adjusted Consequence Model adds additional covariates intended to model the aspects of suppression and egress that were feasible to account for with the available data.

Supplementing the Wildfire Suppression and Public Egress Model descriptions in the following sections, *Appendix 6.3* presents example Adjusted Consequence Model table data calculated for the 2018 Dixie Fire. Note that the data in the appendix was determined from intermediate development models, not the final WFC v4, and are only for illustrating the relative impacts of the consequence adjustment models.

4.1 Wildfire Suppression Impact Model

The Wildfire Suppression Impact Model was investigated and developed in response to a WMP 2023 commitment to consider the effect of wildfire suppression activities on ignition consequence. A major challenge for modeling suppression is the extreme difficulty of understanding historical state, regional, and local responses to ignition events and anticipating how future ignitions will be managed. After extensive research, the fraction of surviving structures within a burn area was selected as an observable proxy for suppression effectiveness.

Wildfire suppression impacts on consequence need to consider factors such as:

- Policy issues that originate from the responsible management authority for a wildfire location and reflect their mandates, priorities, and objectives for suppressing a wildfire.
- The location and availability of firefighting resources that can be allocated during a wildfire. Resource allocation decisions can be affected by concurrent fires or other public needs, accessibility to roads, terrain issues, etc.
- The real-time decision-making by personnel in the field as fire captains with varying degrees of experience evaluate evolving weather conditions, fire conditions, and threats to life and property.

The feasibility of capturing suppression complexities in a model is limited by the usually sparse and often complete lack of availability of data relating each of the factors to actual wildfire outcomes. After considerable exploratory research, the Wildfire Suppression Impact Model was developed using the fraction of surviving buildings within a burn area as a proxy for suppression effectiveness.

The Suppression Impact Model uses as its primary input a Technosylva product, the Terrain Difficulty Index (TDI). TDI considers several factors including terrain steepness, equipment delivery and set-up, and distance from major roads, that correlate with the relative challenges faced by firefighters when combatting a wildfire event. The Suppression Impact Model uses the TDI to modify the estimated number of structures destroyed that was predicted by the Base Consequence Model.

4.1.1 Key Developments

The crucial development activity for creating a Wildfire Suppression Impact Model was the determination to use building survival fraction from historical fires as a proxy value for suppression effectiveness.

The primary objective for fighting a wildfire is to protect life and property, with an emphasis on saving lives. Unfortunately, it is difficult to obtain precise data on the successful protection of lives for a given wildfire. However, Wildfire Public Egress Impact Model development, discussed in *Section 4.2* has established that there is a consistent relationship between lives lost and the number of buildings destroyed by a wildfire. Therefore, success at protecting structures, in terms of the fraction of structures undamaged after a wildfire, will also imply success at protecting lives.

The number of structures destroyed by any given wildfire is publicly available through the annual CAL FIRE Red Books. The number, type, and locations of buildings that stood prior to a given wildfire can be obtained from the data records of Open Street Map. From this data, the fractional loss of buildings can be determined for historical wildfires.

4.1.2 Historical Wildfire Suppression Outcome Model

4.1.2.1 Model Structure

The historical wildfire suppression outcome general model structure that was explored for developing the wildfire suppression impact model took the form of:

$$Structure\ Loss\ Fraction\ \cong f(Fuels, Terrain, Weather)$$

Where:

Variable	Description
Structure Loss Fraction	Expected fraction loss of buildings due to wildfire
Fuels	Localized fuel information
Terrain	Localized terrain information
Weather	Localized weather at time of wildfire

The modeling structure was based on the original hypothesis that a wildfire in a remote, difficult terrain, with abundant, dry fuels, and with extenuating weather like high wind and temperature would lead to suppression difficulties and therefore more building loss.

4.1.2.2 Training Data

The training data for the historical wildfire suppression outcome model was assembled from two sources:

- CAL FIRE Red Books
- OpenStreetMap

The CAL FIRE Red Books are annual publications on the outcomes of major fires that burn more than 300 acres with recorded fire outcomes of acres burned, structures destroyed, and fatalities.

OpenStreetMap is an open source geographic database that includes a buildings data set with location and structure type information. The data set is used to determine the number of existing structures that existed prior to historical wildfires.

4.1.3 Covariate Selection

4.1.3.1 Covariate Pool

The covariates considered and tested for the Historical Wildfire Suppression Impact Model follow.

4.1.3.1.1 Terrain Difficult Index

The Wildfire Suppression Impact Model uses the Terrain Difficulty Index (TDI), a proprietary data product developed and maintained by Technosylva that draws upon their Accessibility, Penetrability, and Fireline Opening Indexes. The TDI, a composite index with values from 1 to 5, uses local topography and other factors to determine speed and access from public roads and fire line feasibility for service territory equipment asset locations. TDI is used for modifying the predicted fraction of surviving structures as a reflection of wildfire suppression effectiveness. Additional information on using

Technosylva's TDI to assess wildfire suppression difficulty is provided in the white paper referenced below[4]. TDI Categories and their descriptions are shown in Table 9.

Table 9 - TDI Categories

Category	Description
1 - Very Low	No accessibility limitations to the firefighting resources, allowing quick deployment of wildfire suppression ground resources
2 - Low	High density of tracks and paths. Terrain conditions allow the deployment of wildfire suppression ground resources
3 - Medium	Roads and tracks are slightly more difficult to access, and terrain is mildly difficult with increasing slopes
4 - High	Low density of roads/tracks in the area. Difficult terrain access with limitations to ground travel
5 - Extreme	Very low density of tracks/roads to support strategies. Highly complex terrain conditions including high-slope areas limit the use of heavy equipment

4.1.3.1.2 Fuel Conditions

Fuel conditions from the PG&E Meteorology team, including live and dead 10-hr, 100-hr, and 1000-hr fuel biomass and fuel moisture levels.

4.1.3.1.3 Weather Conditions

Weather condition assessments from PG&E Meteorology, especially those that pose adverse conditions for suppression, such as relative humidity (RH), wind speed (WS), etc.

[4] Assessing the suppression difficulty of wildland fires for initial attack response (Cardil et al.), December 11, 2025.

4.1.3.2 Fitted Historical Wildfire Suppression Outcome Model

After evaluation, a binomial regression algorithm was selected to model historical wildfire outcomes. The model took the form of:

$$Log\ Odds\ of\ (Fractional\ Structure\ Loss) \cong a * TDI + b * WS + c * LFM + intercept$$

Where:

Variable	Description
Structures Destroyed	Expected number of structures destroyed by wildfire
Structures	Existing structures
LFM	Live fuel moisture of chamise vegetation smoothed to 1 km radius
TDI	Technosylva Terrain Difficulty Index
WS	Wind speed in mph at 300 m above the surface
a, b, c, intercept	Regressed coefficients

Table 10 provides an abridged summary of the model regression results.

Table 10 - Historical Fire Suppression Outcome Model Regression Results

Covariate	Coefficient	P-value
TDI (a)	1.3323	0.000
Wind Speed (b)	0.1100	0.000
Live Fuel Moisture (c)	-0.0774	0.000
intercept	-0.8676	0.000

Inclusion of TDI improves the predictive power of the Wildfire Suppression Model and is the single best performing covariate in the model. As is appropriate for a model of its type, error in model predictions is quantified via residual deviance. *Table 11* provides statistical deviance ratios of the model covariates. The null model is based on the average structure loss across historical fires (no explanatory covariates). Since total deviance is a measure of model error, improved models have ratios less than 1, and a perfect model would have zero total deviance and a ratio of 0.

Table 11 - Wildfire Suppresion Model Covariate Performance

Model	Deviance Ratio
Null	1.000
Wind Speed	0.980
TDI	0.814
LFM	0.970
Full	0.755

Referring to *Figure 10*, from the regression results, it can be observed that the TDI value is most critical to understanding historical fire suppression in terms of fractional building loss. The TDI coefficient is an order of magnitude more important that LFM and WS to modeling the historical wildfires. The model also confirms a common sense of understanding of TDI and wildfire suppression, where higher TDI values, and therefore more remote, rugged locations, will result in a higher fraction of wildfire building loss. Inclusion of TDI improves the predictive power of the Wildfire Suppression Model and is the single best performing covariate in the model.

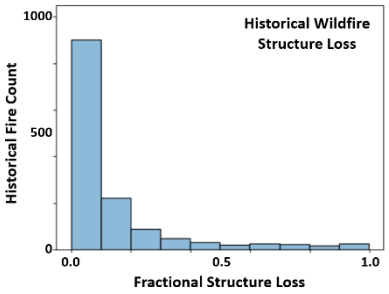

Figure 10 - Historical Wildfire Suppression Outcomes

The Suppression Impact Model is built by applying the Historical Wildfire Suppression Model to perform a series of what-if predictions at each historical fire location to examine the change in expected outcome in response to evaluating alternative TDI levels, 1 through 5.

Figure 11 visualizes the predicted wildfire outcomes for TDI level 1, 3, and 5. TDI level 1, the lowest level, outcomes skew to dramatically lower fractional structure loss when compared to the historical outcomes. TDI level 3, the middle level, shifts expected consequence significantly higher. Finally, TDI level 5, the highest level, predicts outcomes that are likely to lead to almost complete structure loss for a wildfire.

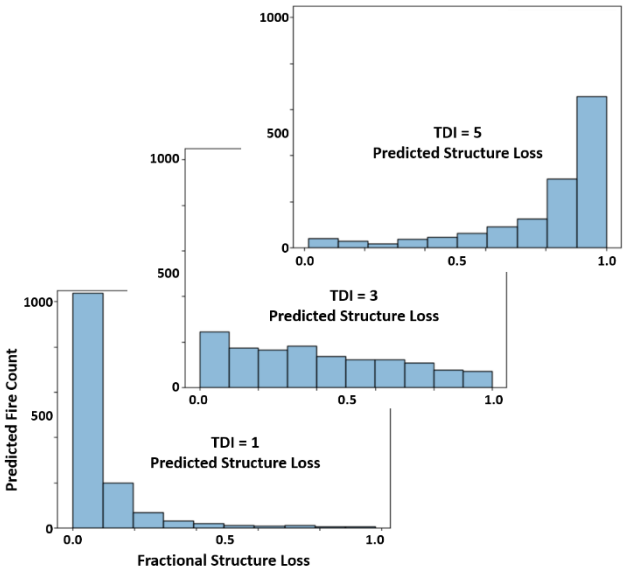

Figure 11 – TDI Level Predicted Wildfire Outcomes

The predicted wildfire outcomes for the alternative TDI levels can also be compared to the historical wildfire outcomes by determining their mean consequence values using the MAVf algorithm. *Table 12* reports the mean wildfire consequence values for the historical and predicted wildfire outcomes. As expected, as terrain becomes more rugged and remote and the TDI level increases, the consequence for predicted outcomes becomes more severe.

Table 12 - TDI Level Consequence

TDI Level	Consequence
Historical	312.1
1	272.4
2	309.9
3	361.6
4	425.9
5	474.7

4.1.3.3 Historical Wildfire Suppression Outcome Model Application

The Historical Wildfire Suppression Outcome Model is applied to each historical fire to examine how TDI level would have impacted the number of buildings destroyed. The integration of suppression data from the analysis of the historical fires to construct a final consequence model is described in Section 4.3.

4.2 Public Egress Impact Model

The Wildfire Public Egress Impact Model was researched and developed in response to a WMP 2023 commitment to consider the effect of the ability of the public to leave the path of wildfire on the final consequence of an ignition event. Determining the likely success of egress is a challenge as there is no concrete historical data that can be used to train a model. However, research showed that wildfire fatalities mostly occur inside structures and the number of fatalities is highly correlated with the number of structures destroyed. Therefore, the Wildfire Public Egress Impact Model was built to predict the number of fatalities per structure destroyed by a wildfire.

A major challenge for modeling egress is the difficulty of understanding historical state, regional, and local responses to ignition events and anticipating how future ignitions will be managed. Public egress impacts on consequence need to consider factors such as:

- Policy issues that originate from the responsible management authority for a wildfire location and reflect their mandates, priorities, and objectives for initiating and managing a public evacuation in response to a wildfire.
- Number of egress routes available, volume capacity of egress routes, and public mobility in the predicted path of a wildfire.
- The number of people that choose, or conversely refuse, to follow an evacuation order.
- The real-time decision-making by public safety personnel in response to evolving weather conditions, fire conditions, and threats to life and property.

The feasibility of capturing public egress complexities in a model is limited by the usually sparse and often complete lack of data relating each of the factors to actual wildfire outcomes. After considerable research, the Wildfire Public Egress Impact Model was developed to predict the ratio of the number of fatalities that will occur per number of structures burned as a proxy for egress effectiveness.

Egress research revealed a definite bias for those with mobility issues due to age, medical conditions, or vehicle availability as most likely to become wildfire victims. The Egress Impact Model was trained to consider the Access and Functional Needs (AFN) index as a proxy for mobility issues. The model predicts a relatively higher ratio of fatalities to structures destroyed in areas where there are higher concentrations of the public characterized as AFN.

The Public Egress impact is interactive with the Wildfire Suppression impact. If the Suppression Impact lowers the relative number of structures destroyed, then it will also lower the expected number of fatalities due to egress issues.

4.2.1 Key Developments

The critical development activity for creating a Wildfire Public Egress Impact Model was the decision to use fatalities-per-structure-burned ratio as a proxy value for suppression effectiveness. This modeling decision was based on a key assumption that when a structure burns due to a wildfire, its occupants must either evacuate or fall victim to the fire.

Several potential contributors to Egress impacts were investigated, of which personal mobility and roadway congestion were of particular interest. Interestingly, it was discovered that personal mobility was the important quantifiable factor. While roadway congestion is believed to play some role, model regressions failed to find a significant relationship, most likely due to the small number of fires with actual roadway fatalities.

4.2.2 Historical Wildfire Egress Outcome Model

4.2.2.1 Model Structure

The historical wildfire egress outcome general model structure that was explored for developing the wildfire egress impact model took the form of:

$$Log\ Odds\ of\ (Fatality\ Fraction) \cong f(Road\ Miles\ per\ Capita, Mobility)$$

Where:

Variable	Description
Fatality Fraction	Expected fractional loss of life per buildings burned
Road Miles per Capita	Localized route capacity information
Mobility	Localized public mobility information

4.2.2.2 Training Data

Training data for the Historical Wildfire Egress Outcome Model was assembled from NASA VIIRS data. There were 170 wildfires where either burned structures or fatalities were recorded, which became the training data set for Public Egress Impact Model development.

4.2.3 Covariate Selection

With only 170 wildfires available for the training data set, only a limited number of variables could be used for any given model evaluation to prevent regression model overfit. Covariate selection was strongly influenced by exploratory analysis of historical fires such as Tubbs, Nunns, and Camp. *Figure 12* is an illustration of an egress covariate analysis of the 2018 Camp Fire. Fire victims were found in structures and the overwhelming majority of people in vehicles, 99.98%, reached safety.

The 2018 Camp fire provides an interesting case study for egress[5]:

- 50,000 people in about 25,000 vehicles evacuated Paradise, Concow, Magalia and the surrounding area.
- 19,500 buildings were destroyed.
- The median age for Camp Fire victims was 72 years.
- 85 fatalities were attributed to the fire.
  - 67 victims were age 64 or above.
  - 73 victims were found in or near their own home, and many had identifiable disability or mobility problems.
  - 5 victims were on foot with no evidence they were ever in a car.
  - Only 9 victims were found in a car or near their car having fled on foot.
- Multiple evacuation routes became completely obstructed.
  - 2 of 4 major routes from Paradise were completely obstructed for most of the evacuation period.
  - Evacuees experienced severe gridlock with many taking over 10 hours to travel just a few miles.
  - 23 burnover events impacted the roadways.
  - 230 vehicles were abandoned major roadways.

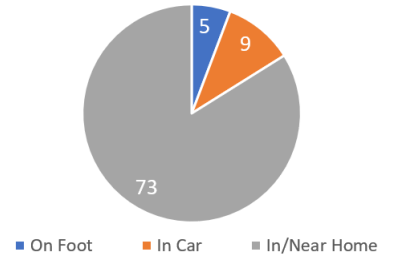

Figure 12 - Camp Fire Fatality Locations

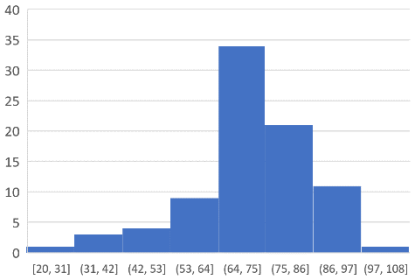

Figure 13- Camp Fire Fatalities by Age

To summarize, 86% of the Camp Fire victims were found in structures and the overwhelming majority of people in vehicles, 99.98%, reached safety. *Figure 13* shows an age distribution for the Camp Fire fatalities.

4.2.3.1 Covariate Pool

The Camp Fire case study led to considering personal mobility proxy covariates for the Historical Wildfire Suppression Outcome Model:

- Census data on older resident demographics
- PG&E data on Medical Base Line needs (MBL) customer fraction
- PG&E data on Access and Functional Needs (AFN) customer fraction
- Road congestion

Census data and MBL, while producing modest relationships for the historical fires, were rejected as covariates. Census data is not available with enough fine granularity to predict with spatially. The percentage of MBL customers in the PG&E service territory, 5.8%, was too sparsely distributed to be useful as a covariate.

[5] A Case Study of the Camp Fire - Notification, Evacuation, Traffic, and Temporary Refuge Areas (NETTRA), July 18, 2023

Potential road congestion, which is often suggested as a covariate by subject matter experts such as firefighters and wildfire analysts, was also rejected as a variable mostly due to a lack of usable information pertinent to modeling. A road availability proxy value available from Technosylva was tested but resulted in unstable regressions with poor covariate significance. While there may be a relationship between road congestion and wildfire fatalities, a means to successfully model the relationship eluded the development for this version of Egress impact modeling.

AFN was selected as a covariate for the Wildfire Public Egress Impact Model. AFN is an all-encompassing term for any PG&E customer who:

- Is classified as MBL
- Has a mobility issue
- Is hearing-impaired
- Is visually impaired
- Is a life support customer
- Self-identified as vulnerable
- Over the age of 65

Approximately 33% of the PG&E customer base has an AFN status. Therefore, AFN provides a much more detailed view of demographic impacts that could influence wildfire evacuation. Even so, modeling results between AFN and wildfire fatalities were modest, but stronger than for the rejected covariates.

The AFN value used in the egress model is derived from PG&E service point location data and represents the proportion of the nearby population with AFN that may make evacuation more challenging during a wildfire. The model applies a spatial smoothing approach, called Gaussian convolution, that allows nearby populations to contribute to the AFN value, while giving less weight to populations farther away. This reflects the fact that a wildfire can threaten communities beyond its ignition point. A 10-kilometer smoothing distance was selected to approximate the population that could be affected by a wildfire, based on the typical first-day spread distance of historical fatal fires.

In some remote areas, there are very few customers or residents, making it difficult to reliably estimate the local proportion of people with Access and Functional Needs (AFN). To address this, the model applies a stabilization approach that prevents AFN values in sparsely populated areas from falling below a reasonable baseline (the service territory average AFN value). This helps produce more reliable estimates where data are limited, while having little to no effect in more densely populated areas (defined as areas with more than one person per square kilometer), where sufficient local information is available.

4.2.3.2 Fitted Historical Wildfire Egress Outcome Model

After evaluation, a binomial regression algorithm was selected to model historical wildfire outcomes. The model took the form of:

$$Fractional\ Fatalities\ \cong a * AFN + b * WS + intercept$$

Where:

Variable	Description
Fractional Fatalities	Expected fractional number of fatalities from wildfire
AFN	Blurred Access and Functional Needs value
WS	Wind speed in mph at 300 m above the surface
a, b, intercept	Regressed coefficients

Table 13 provides an abridged summary of the Historical Wildfire Egress Model regression results. *Figure 14* illustrates the relative change in fatality rate as a function of AFN fraction deciles. The table has been normalized to the 5th decile result. Inclusion of AFN improves the predictive power of the Wildfire Egress Model.

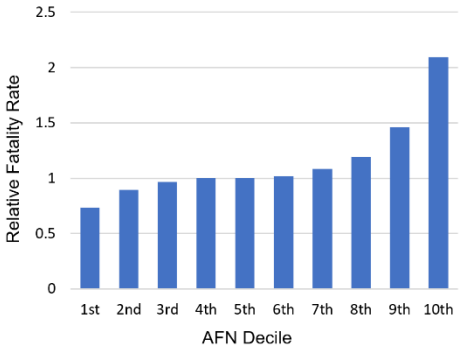

Figure 14 - Fatality Rate - AFN Relationship

Table 13 - Historical Egress Outcome Model Regression Results

Covariate	Coefficient	P-value
AFN (a)	3.0006	0.000
Wind Speed (b)	0.0133	0.000
intercept	-7.2095	0.000

Table 14 below provides the total statistical deviance ratio of the model with the AFN covariate, which improved model predictive performance. The "null" model is based on the average number of fatalities per-structure across historical fires with fatalities (no explanatory covariates). Since total deviance is a measure of model error, improved models have ratios less than 1, and a perfect model would have zero total deviance and a ratio of 0.

Table 14 - Wildfire Egress Model Covariate Performance

Model	Deviance Ratio
Null	1.000
Wind Speed	0.965
AFN	0.967
Full	0.898

4.2.3.3 Historical Wildfire Egress Model Application

The Historical Wildfire Egress Outcome Model is applied to each historical fire to examine how AFN decile level would have impacted the number of fatalities. The integration of egress data from the analysis of the historical fires to construct a final consequence model is described in *Section 4.3*.

4.3 Adjusted Consequence Methodology

Base consequence for any specific fire season day, as discussed in *Section 3*, is determined from a combination of location HFRA membership, Dry Wind Conditions (DWC), and Predicted Destructive (PD) conditions. These three stratifying variables identify eight distinct partitions for wildfire consequence. The eight partitions are referred to using a descriptive shorthand of their respective true or false statuses in the order of HFRA, DWC, Predicted Destructive (PD). Hence, the consequence partition for a location in HFRA, on a day not under Dry Wind Conditions, but on a Predicted Destructive day is referred to as "T/F/T".

The consequence adjustment methodology expands each of the eight base consequence partitions from a single consequence value to a 5 by 10 matrix of consequence reflecting the TDI level and AFN Decile for a grid asset location. The matrixed consequence values are determined by first applying the Suppression Impact Model described in *Section 4.1*, then the Egress Impact Model described in *Section 4.2*.

Figure 15 provides an overview of how Suppression and Egress impact the predicted outcomes that are input to the MAVf to determine a consequence value for a location on a particular day.

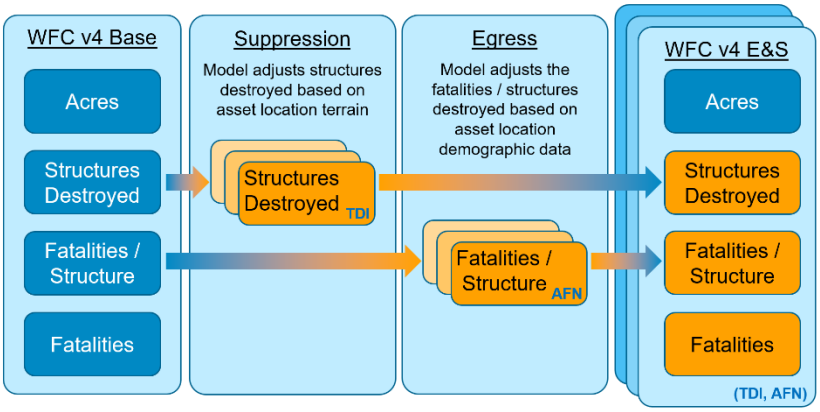

Figure 15 - Overview of Wildfire Consequence with Suppression and Egress Impacts

4.3.1 Consequence Regime Table Construction

The Adjusted Consequence Partition Tables are constructed by evaluating each of the historical fires that ignited under the specific partition conditions. This process is repeated for each historical fire recorded for a consequence partition. Finally, the consequence values for each TDI – AFN combination are averaged across all of the partition historical fires, resulting in a final consequence matrix as shown in *Table 15* for the T/F/T partition. Note that as the majority of historical fires in the T/F/T partition are not catastrophic that, unlike the Dixie Fire, the average consequence values are much lower.

Table 15 - T/F/T Consequence Regime Table

TDI Level	AFN Decile									
	1st	2nd	3rd	4th	5th	6th	7th	8th	9th	10th
1	45	45	45	45	45	45	45	45	46	47
2	98	99	99	99	99	99	99	100	101	104
3	217	218	219	219	219	219	220	221	224	231
4	409	412	414	414	414	415	416	418	424	438
5	621	626	628	629	629	630	632	636	644	666

The T/F/T consequence regime Suppression and Egress impacts relationship can also be visualized graphically, producing the plot shown in *Figure 16*. Note that the plotted point colors are coordinated with the row colors of *Table 15* above. On the plot it is easy to understand how both TDI Level and AFN Decile impact the relative consequence value for a consequence regime.

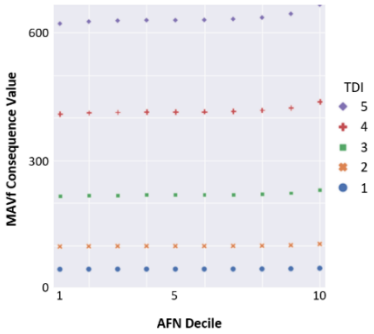

Figure 16 - T/F/T Consequence Partition

Figure 17 below displays the four consequence partitions generated for WFC v4 for assets located inside the HFRA for the four possible combinations of Dry Conditions (DWC) and Predicted Destructive (PD). The y-axis axis is the consequence value range that is different for each partition, with three orders of magnitude difference between highest and lowest consequence values.

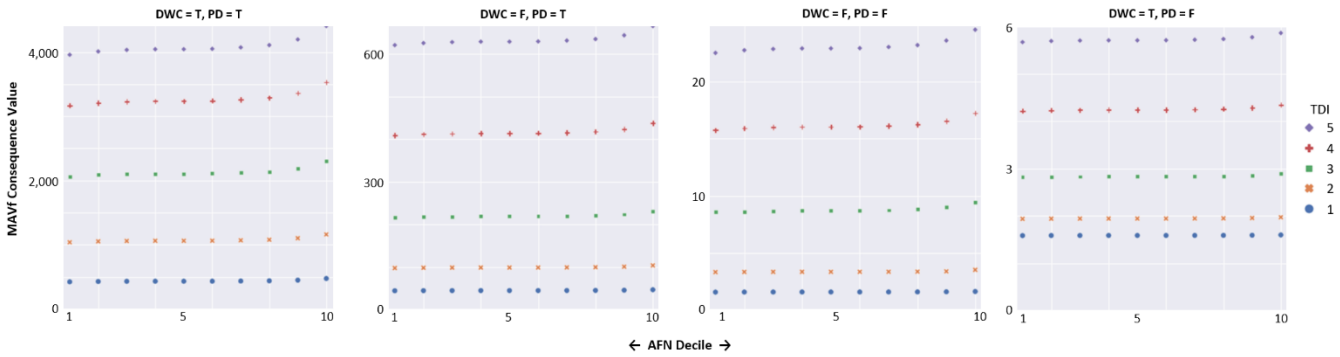

Figure 17 - Consequence Partitions for HFRA Asset Locations

Figure 18 displays the four consequence partitions generated for WFC v4 for assets located outside the HFRA for the four possible combinations of Dry Wind Conditions (DWC) and Predicted Destructive (PD). The y-axis consequence value range is different for each partition, with an order of magnitude difference between highest and lowest consequence values.

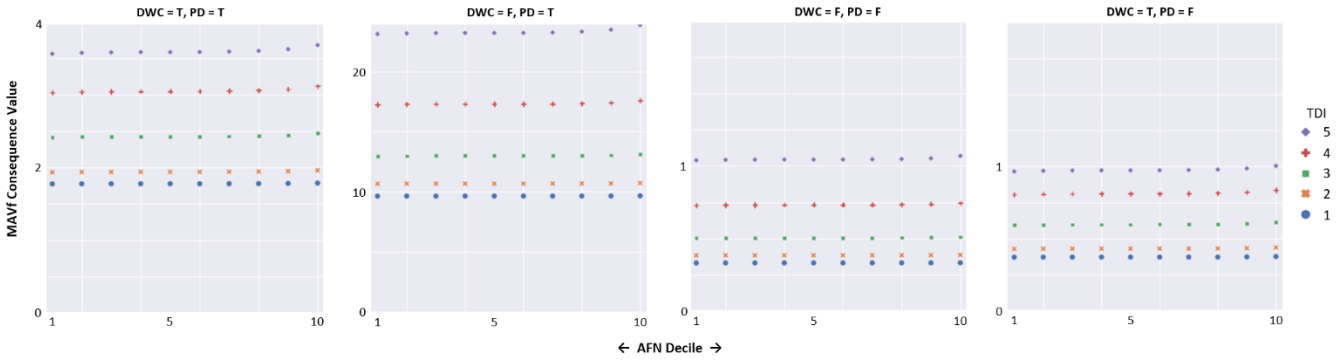

Figure 18 - Consequence Regimes for non-HFRA Asset Locations

Note that, as expected, there is a considerable disparity between high consequence partition values for HFRA versus low values for non-HFRA asset locations for similar Dry Wind Conditions (DWC) and Predicted Destructive (PD) states.

4.3.2 Consequence Regime Table Application

Like the Base Consequence Table, the Adjusted Consequence Partition tables are used to assign adjusted consequence values for grid asset locations. A grid asset location adjusted consequence value is the average adjusted consequence value over every wildfire season day from 2012 through 2022. Each wildfire season is defined as the 183 days from June 1st through November 30th. With 11 fire seasons covering 2012 through 2022, daily consequence values can be assigned to a total of 2,013 days.

For example, take an asset located in HFRA, with a TDI level of 2, and is at the 4th AFN decile. For a day with no Dry Wind Conditions (DWC) but with Predicted Destructive (PD) conditions, the assigned adjusted consequence value is 99, which can be confirmed by checking *Table 15*. However, on a higher risk day with both Dry Wind Conditions (DWC) and Predicted Destructive (PD) conditions, the assigned adjusted consequence value would be 1,063. A consequence value of 99 in a HFRA without Dry Wind Conditions (DWC) but with Predicted Destructive (PD) conditions presents lower fire spread risk than a consequence value of 1,063, which meets both Dry Wind Conditions (DWC) and Predicted Destructive (PD) thresholds. Extending this logic out for a full set of wildfire season days, the average consequence value for an asset location can be calculated as shown in *Table 16*.

Table 16 - Asset Location Adjusted Consequence Value Example

HFRA	Dry Wind Conditions	Predicted Destructive	TDI Level	AFN Decile	Adjusted MAVf	Fire Season Days	MAVf Sum
True	True	True	2	4	1063	50	53,150
True	True	False	2	4	1.94	150	291
True	False	True	2	4	99	550	54,450
True	False	False	2	4	3.35	1,263	4,231
Total						2,013	113,122
Average							**56.2**

Note: Some variables in the source document are defined conceptually or by threshold but do not state a physical unit explicitly (for example, Flame Length, Rate of Spread, and Live Fuel Moisture in the regression summaries). In those cases, this summary labels the unit as not stated rather than inferring one.

Referring back to the asset location base consequence example value provided in *Table 8* of *Section 3.5*, the Egress and Suppression adjustments for TDI level and AFN decile have modified the average asset location consequence from a base value of 63.4 to an adjusted value of 56.2. This is a contributing factor to the flattening of the overall risk curve for WDRM v4.

4.4 Adjusted Consequence Impacts

As described previously, adjusted consequence values are determined as an extension of the base consequence partitions. Therefore, an examination of the adjusted and base consequence values was performed to understand and validate the consequence adjustment for wildfire suppression and public egress.

Figure 19 provides a view into where the adjusted consequence shifted values relative to the base consequence in the western Sierra Mountains. Most notable are the easily distinguished yellow circuit lines indicating a significant relative consequence increase for the more remote and rugged valleys. The increase largely reflects the wildfire suppression impact and reflects the higher TDI levels assigned to these areas. Conversely, foothill areas, especially those with significant populations, generally have lower relative consequence due to proximity to firefighting resources and better access to for initial ignition response.

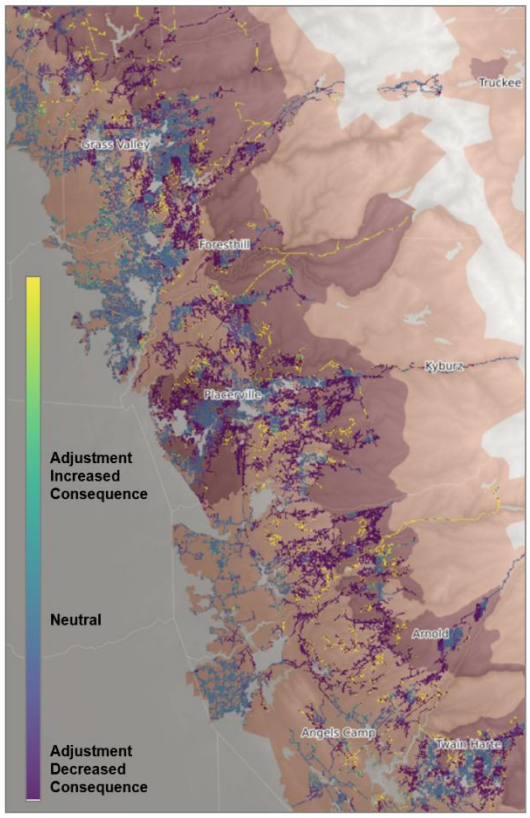

Figure 19 - Relative Adjusted Consequence Differential

The WFC Model directly supports the WDRM, therefore, consequence model changes are typically analyzed using aggregations of consequence pixel values to System Hardening's mitigation work planning unit, Circuit Segments (CS). *Figure 20* is a plot of adjusted versus base consequence rankings (where the highest rank is 1) for the top 2,500 circuit segments. On this plot, the blue diagonal line represents where the CS consequence ranks are the same for both the adjusted and base values. Suppression and egress adjustments can drive consequence up or down. Any point above the blue diagonal represents a CS where the adjusted consequence rank is lower (e.g., rank equals 1 represents the highest fire spread risk) than the base consequence rank, while any point below the diagonal represents a CS where the adjusted consequence rank is higher (e.g., rank equals 99, represents a lower fire spread risk compared to ranks 1-98) than the base consequence rank. Note that the CS point color represents the length of the CS with longer CS represented by darker points.

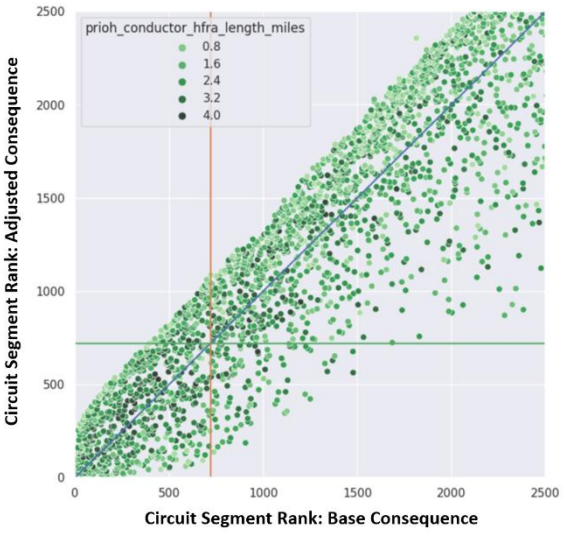

Figure 20 - Adjustment Impact on Circuit Segment Consequence

Keep in mind that a consequence rank change could be the result of two different reasons. First, the change could be due to a significant delta between the adjusted and base consequence value. Second, while the adjusted and base consequence values may be almost the same, other closely ranked circuit segments may have seen very significant changes that shifted the relative rankings.

Another consequence validation analysis was to look at how the adjusted and base consequence model values impact the System Hardening risk buydown curve. The risk buydown curve provides an estimate of how many miles of primary overhead conductor must be undergrounded or harden to mitigate wildfire risk for the electric distribution grid.

Figure 21 contrasts the buydown curves for adjusted and base consequence. The introduction of the wildfire suppression and public egress flattened the risk buydown curve when compared with base consequence. The significance of the flattened curve is that it will take more miles of mitigated risk to achieve reduction targets. The base consequence curve estimates that it will take about 7,500 miles of work to mitigate 60% of wildfire risk, whereas the adjusted consequence curve estimates that it will require 10,000 miles of work to mitigate the same amount of risk. This was not the original expectation for adding the wildfire suppression and public egress impacts, resulting in additional efforts to validate the results and confirm the model development.

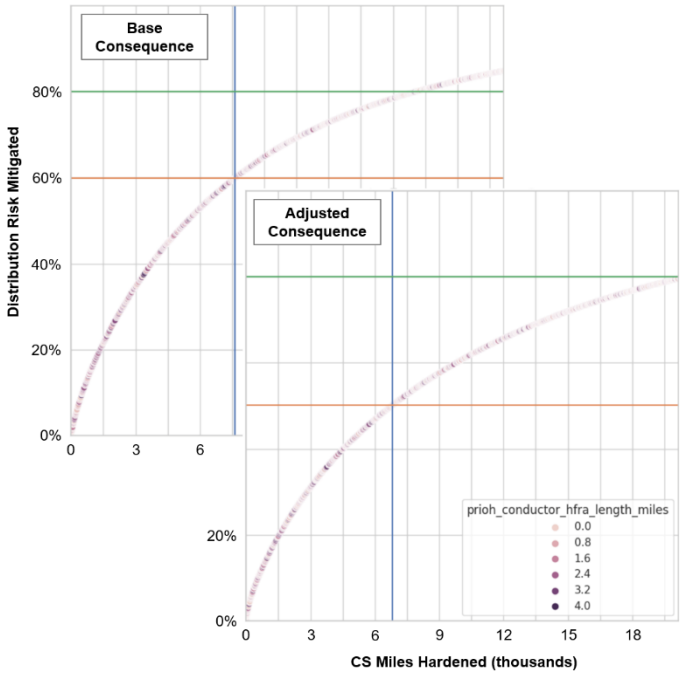

Figure 21 - System Hardening Risk Buydown

5 Future Plans

PG&E has released new versions of the WDRM, and therefore the WFC, on an annual cycle. In the future, WDRM releases will be aligned with the WMP filing schedule rather than annually. Future WFC Model versions will aim to improve on existing features and capabilities while addressing unquantified risk, including:

- Further improve the capture, detail, maintenance, and curation of data sets including supplementing VIIRS historical wildfire satellite data with additional sources
- Continue to refine egress and suppression impacts and new features for vulnerable communities and Wild Urban Interface (WUI) fire consequence
- Integrate modified Technosylva historic wildfire spread data to account for Urban Conflagration
- Account for temporal alignment between probability of ignition and consequence
- Quantify uncertainty in risk around consequence values
- Explore ways to incorporate and quantify the impact of climate change on consequence

Figure 22 presents an overview of the 3-year Wildfire Risk Products Plan, with planned improvements for the WFC highlighted in blue.

6 Appendix: Special Topics

6.1 National Weather Service Red Flag Warning Criteria

Red Flag Warnings (RFW) are issued for a Fire Weather Zones, as shown in *Figure 23*, by the National Weather Service (NWS) when there are weather conditions that would intensify fires.

As noted in Section *3.3.2* on the Dry Wind Conditions covariate, the criteria to declare a Red Flag Warning varies by Fire Weather Zone.

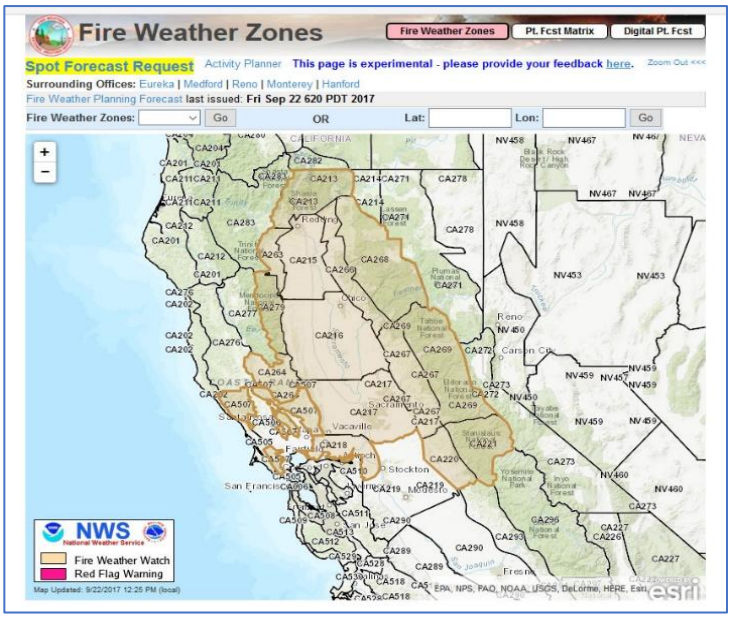

Figure 23 - NWS Fire Weather Zones

Table 17 and *Table 18* provide a summary of the different limit criteria in effect for the NWS Fire Weather Zones.

Table 17 - NWS Fire Weather Zone RFW Limit Criteria

Zones	Description	Criteria
226-228, 230, 232, 260-262	Southern California desert area excluding the Colorado River Valley	Relative humidity <= 15% and wind gusts >= 35 mph for 3+ hours
229,231	Colorado River Valley	Relative humidity <= 15% and sustained winds (@20 ft) >= 20 mph or frequent gusts >= 35 mph for 3+ hours
298, 299, 259	Antelope Valley and SE Kern County deserts	Relative humidity <= 15% and sustained winds (@20 ft) >= 25 mph for 8+ hours
234-258, 288-297	Southern California from mountains westward	EITHER Relative humidity <= 15% and sustained winds >= 25 mph or frequent gusts >= 35 mph for 6+ hours OR Relative humidity <= 10% for 10+ hours
214, 270-273, 278, 284, 285	Northern California East of Cascade/Sierra Crest and Western Great Basin including the Modoc Plateau	TAHOE MANAGEMENT BASIN Wind gusts >= 30 mph And relative humidity <= 20% For 3+ hours REMAINDER Wind gusts >= 30 mph And relative humidity <= 15% For 3+ hours

6.3 Dixie Fire Adjusted Consequence Example

The following examples were developed for 2021 Dixie Fire to illustrate how base and adjusted consequence are calculated for a historical fire. The data presented in this section came from development version of the model and may not match the final WFC v4. This example highlights the difficulty of predicting future outcomes of large and long-lived fires: the Dixie Fire's evolution was determined by conditions far from the point of origin, dynamic allocation of firefighting resources, and a specific sequence of weather conditions that could not be known at the time or location of ignition. Dixie destroyed fewer threatened homes and produced no civilian casualties. As a result, the actual destruction was lower than would be inferred from other fires under similar conditions. The WFC v4 predicted more fatalities for Dixie's structure count than were actually realized. Combined with the MAVf non-linear response, predicted consequences for a hypothetical Dixie-like fire at various TDI and AFN levels were indeed greater than observed.

6.3.1 Dixie Fire Attributes

Table 20 is a summary of conditions and outcomes for the Dixie Fire based on ignition location to gain insight into the impacts of suppression and egress adjustments.

Table 20 - Dixie Fire Summary

Statistic	Value
HFRA	True
Dry Wind Condition	False
Predicted Destructive	True
TDI Level	2
AFN Decile	4
Acres Burned	963,309
Buildings Burned	1311
Fatalities	1
MAVf	13106

6.3.2 Wildfire Suppression Model TDI Level Impact

The Wildfire Suppression Model predicts the number of structures destroyed for the five TDI levels. Referring back to *Table 20*, the Dixie Fire started in an area with a TDI level of 2 and destroyed 1,311 structures. Using the Suppression Model, it can be estimated how TDI level would have impacted the number of structures destroyed by the fire, as shown in *Table 21*.

Table 21 - Dixie Fire Suppression Predictions

TDI Level	Buildings Destroyed
Actual	1311
1	531
2	1311
3	3021
4	6082
5	9985

6.3.3 Public Egress Predictions for AFN Deciles

The 2021 Dixie Fire is shown for illustration purposes using an earlier version of fire data from the development version of the model. The Public Egress Model predicts the number of fatalities for the ten AFN deciles. Referring back to *Table 20*, the Dixie Fire started in an area with a TDI level of 2, an AFN decile level of 4, and resulted in one fatality. Using the Public Egress Model, it can be estimated how AFN decile level would have impacted the number of fatalities as shown in *Table 22*.

Table 22 - Dixie Fire Egress Predictions

AFN Decile	1st	2nd	3rd	4th	5th	6th	7th	8th	9th	10th
Fatalities	2.3	2.8	3.1	3.2	3.2	3.2	3.4	3.8	4.6	6.6

6.3.4 Wildfire Suppression and Public Egress Adjustment Impact on Hypothetical Outcomes

The Dixie Fire started in HFRA, without Dry Wind Conditions (DWC), on a Predicted Destructive (PD) day (T/F/T). Using the Suppression and Egress Impact Models, the number of structures destroyed for a given TDI level and the expected fatalities based on AFN Decile can be predicted, resulting in the matrix of hypothetical outcomes shown in *Table 23*.

Table 23 - Dixie Fire Predicted Suppression & Egress Outcomes

TDI Level	Structures Destroyed	Expected Fatalities by AFN Decile									
		1st	2nd	3rd	4th	5th	6th	7th	8th	9th	10th
1	531	0.9	1.1	1.2	1.3	1.3	1.3	1.4	1.5	1.9	2.7
2	1311	2.3	2.8	3.1	3.2	3.2	3.2	3.4	3.8	4.6	6.6
3	3021	5.4	6.5	7.0	7.3	7.3	7.4	7.9	8.7	10.6	15.2
4	6082	10.8	13.1	14.2	14.7	14.7	14.9	15.9	17.5	21.4	30.7
5	9985	17.7	21.5	23.3	24.1	24.1	24.5	26.1	28.7	35.1	50.3

Predictions are converted into consequence values using MAVf, producing the *Table 24* matrix.

Table 24 - Dixie Fire Predicted Suppression & Egress MAVf Consequence

TDI Level	AFN Decile									
	1st	2nd	3rd	4th	5th	6th	7th	8th	9th	10th
1	7145	7153	7156	7158	7158	7159	7162	7167	7181	7212
2	13180	13199	13208	13212	13212	13214	13222	13235	13268	13344
3	26419	26463	26484	26493	26493	26497	26516	26618	26898	27560
4	50410	50741	50894	50963	50965	50999	51140	51369	51933	53265
5	81348	81892	82143	82256	82260	82315	82547	82923	83848	86036

6.4 Wildfire Consequence Fire Spread Risk Example

Table 25 below provides an illustrative example of Wildfire Consequence scores based on fire spread risk levels Low, Medium, and High; components of Predicted Destructive (PD) including the Fire Potential Index (FPI-R) score, Flame Length (FL), and Rate of Spread (RoS); components of Dry Wind Conditions including Wind Speed (WS), Dry Fuel Moisture (DFM), and Relative Humidity (RH); High Fire Risk Area (HFRA); Access and Functional Needs (AFN) index adjustments; and Terrain Difficulty Index (TDI) adjustments.

Table 25 - Wildfire Consequence Fire Spread Risk Example

WILFIRE CONSEQUENCE										
	PD			DWC			HFRA	Access and Functional Needs (Egress Adjustment)	Terrain Difficulty Index (Suppression adjustment)	Wildfire Consequence (unitless relative measure)
	FPI-R	FL	ROS	Wind Speed	10-hr Dry Fuel Moisture	Relative Humidity				
Low Fire Spread risk	R1	2 ft	5 Ch/hr	5 mph	15%	60%	N	20-30% of the PG&E customer base are AFN customers	1	25
Medium Fire Spread risk	R2	3 ft	10 Ch/hr	12 mph	10%	40%	Y	40-45% of the PG&E customer base are AFN customers	3	400
High Fire Spread risk	R5	5 ft	12 Ch/hr	20 mph	5%	20%	Y	60-70% of the PG&E customer base are AFN customers	5	800

Executive Summary

The Wildfire Distribution Risk Model (WDRM) is used by PG&E to quantify and categorize wildfire risk from overhead distribution network assets. The model predicts the relative risk of a wildfire occurring during an annual fire season as the result of an ignition related to distribution grid assets. The relative wildfire risk results produced by the WDRM informs the PG&E Wildfire Mitigation Plan (WMP) as well as specific mitigation program work plans to help realize the company stand, *"Catastrophic wildfires will stop"*.

This document describes WDRM version 4 (v4) development by the Risk and Data Analytics (RaDA) team and highlights improvements implemented over its predecessor, WDRM v3.

WDRM v4 Risk Prediction

Wildfire risk is the combination of two modeled values, the probability, or likelihood, of an ignition event and the likely consequence of an ignition event at a geographical location. Each of these models apply machine learning techniques to historical events, asset attributes, and meteorological information to predict what will occur for a future fire season.

The probability of ignition model represents the likelihood of an ignition event occurring during a single fire season. The probability of ignition is predicted in two steps. First, the probability of outage (or failure) for a fire season is estimated for a variety of asset types and failure modes. These are often referred to as subset models. Second, the probability of an ignition given an outage is determined for each asset type and failure model combination. The final probability of ignition result is the multiplication of the probability of outage and probability of ignition given outage model results.

The consequence model projects the severity of fires that are ignited at geographic locations associated with distribution grid assets. The model is trained using historical fire records, fire simulation data from Technosylva, Fire Potential Index (FPI) information from PG&E meteorology, terrain topology, and other attribute data.

Often, wildfire mitigation programs are concerned with addressing the wildfire risk from multiple distribution assets and failure modes, which often require different remedial actions. The WDRM assembles the risk predicted for individual assets and failure modes into composite risk models to support more comprehensive mitigation planning such as system hardening and vegetation management.

WDRM v4 Improvements

WDRM v4 features several significant improvements to the modeling of distribution wildfire risk:

- Improved quality of training and covariate datasets, resulting in a direct impact on model quality.
- Transition of several WDRM v3 equipment asset event probability models from spatial, pixel-based to asset-based.
- Introduction of four new equipment asset-based event probability models.
- Vegetation event probability models were improved with data for tree health and wind direction.
- Wildfire Consequence v4 received several significant upgrades, including 24-hour fire simulations, Technosylva's Terrain Difficult Index, Dry Wind Conditions, and corrections for public Egress and fire Suppression impacts. Wildfire Consequence v4 performance prediction for historical fires improved significantly over Wildfire Consequence v3.4.
- Circuit segment risk rankings are based on risk per primary overhead conductor mile for v4, replacing the mean risk based rankings issued for v3. This change made in response to System Hardening and Undergrounding mitigation team requests.

WDRM v4 Wildfire Risk Insights

WDRM v4 benefited from significant improvements to both the Event Probability Models for outages and ignitions and the Wildfire Consequence Model. As a result of the many contributing model improvements, WDRM v4 produces risk values that show a general flattening of the risk profile for the service territory. The most critical insight is that the WDRM v4 System Hardening composite risk buydown curve requires considerably more primary overhead conductor miles to account for 80% of the HFTD risk, increasing from 10,000 miles for WDRM v3 to 14,600 miles for WDRM v4.

While there are many contributing factors for the flattened risk buydown curve, a principal cause has been changes to the wildfire consequence model driven by improved historical fire datasets, 24-hour fire simulations, Technosylva's Terrain Difficulty Index, the introduction of public Egress and fire Suppression impacts, and the implementation of a revised consequence Multi-Attribute Value function (MAVf). While the new Wildfire Consequence v4 features have improved performance when compared with v3.4, it has also redistributed consequence, and therefore risk, across the service territory, resulting in a much flatter risk buydown curve.

Future Development Plans

The RaDA team has a 3-year risk model product plan targeted at the delivery of the next WDRM version release. While RaDA has historically produced the WDRM on an annual cycle, in the future WDRM version releases will be aligned with the WMP filing schedule. Therefore, this version of the WDRM is planned in support of the 2026 WMP.

WDRM v4 delivered several features planned for 2024 and 2025 development and additional features will be delivered during the remainder of 2024 and 2025. Several new features are planned for delivery in support of the 2026 WMP filing. Substantial efforts are expected to further improve the capture, detail, maintenance, and curation of data sets used for risk models. Future risk modeling will progress beyond informing mitigation work plan development and will provide risk and risk reduction values in support of data driven portfolio level decisions for the Integrated Grid Planning process.

1 Introduction

The Wildfire Distribution Risk Model (WDRM) is used by PG&E to quantify and categorize wildfire risk from overhead distribution network assets. The model predicts the relative risk of a wildfire occurring during an annual fire season as the result of an ignition initiated at the location of a distribution grid asset. The relative wildfire risk results produced by the WDRM supports the PG&E Wildfire Mitigation Plan (WMP) as well as specific mitigation program work plans to help realize the objective, *"Catastrophic wildfires will stop"*.

This document describes WDRM version 4 (v4) development by the Risk and Data Analytics (RaDA) team and highlights improvements implemented over its predecessor, WDRM v3.

1.1 Wildfire Risk Management Ecosystem

PG&E uses several planning and operational risk models for wildfire risk management within its wildfire risk management ecosystem:

- Planning models
  - Enterprise Risk Model
  - Wildfire Transmission Risk Model (WTRM)
  - Wildfire Distribution Risk Model (WDRM)
- Operational models for Public Safety Power Shut-off (PSPS) and Enhanced Power System Settings (EPSS)
  - Distribution OPW and IPW models
  - Transmission Operability Assessment

The outputs of the planning and operational models, along with input from Public Safety Specialists (PSS) and other Subject Matter Experts (SME), are used to form PG&E's Wildfire Mitigation Plan (WMP).

Figure 1 - PG&E Risk Management Ecosystem

The WDRM is the primary risk model that PG&E uses to provide insights to prioritize mitigation work to reduce wildfires initiated by the distribution grid. The WDRM produces predictions of wildfire risk and estimates of risk

reduction for potential mitigation activities. Mitigation program work planners use the WDRM results, along with subject matter expertise and additional information potentially not included in the risk models, as part of their mitigation program work planning tools to develop work plans that systematically reduce wildfire risk while considering constraints such as budget allocation, human and equipment resource capacity, and regulatory commitments.

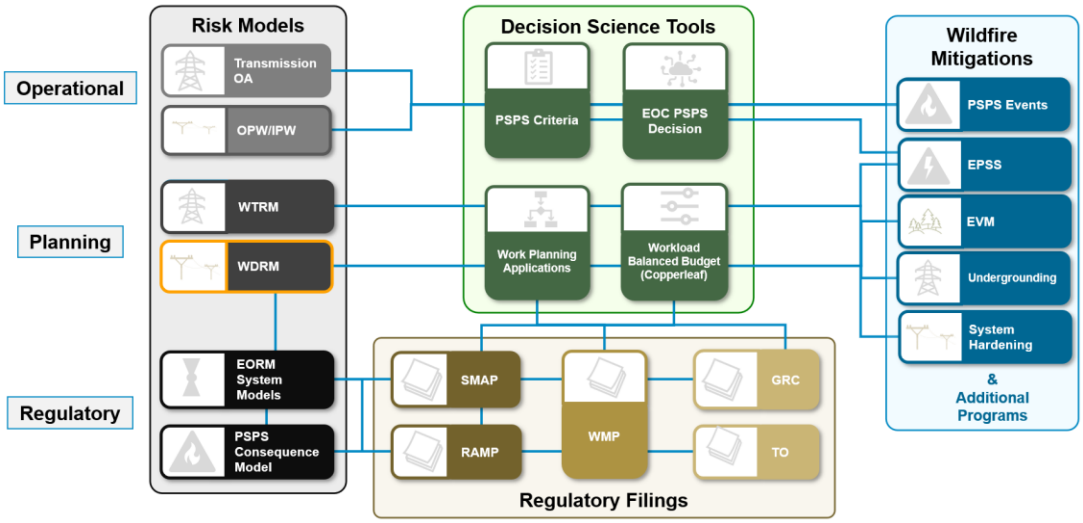

Figure 2 - WDRM Role in Risk Management

Wildfire risk modeling, mitigation work planning, and mitigation work execution occur on overlapping time cycles. *Figure 2* illustrates the expected coordination of the development and execution workflows.

1.2 Wildfire Distribution Risk Model (WDRM)

The WDRM was developed by the PG&E Risk and Data Analytics (RaDA) team to quantify the risk related to PG&E's overhead distribution equipment assets, which consist of overhead transformers, poles and other parts of support structures, conductor lines, and line-related equipment such as interrupters.

The WDRM provides predictions of the where, why, and how much wildfire risk occurs during a wildfire season of June 1st through November 30th.

It is important to understand that since the WDRM is built as a support model for wildfire mitigation planning, the model therefore predicts risk as an aggregate value for an annual fire season. The model does not predict specific risk for shorter time intervals within a fire season such as on a daily or monthly basis. The WDRM model results are relevant

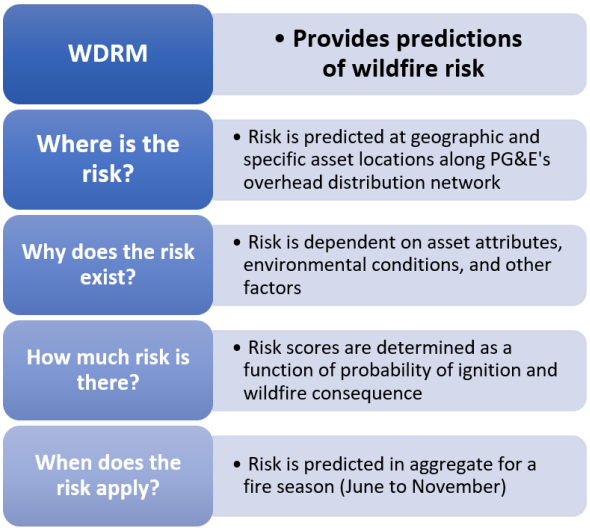

Figure 3 - WDRM Objectives

only for annual and multi-year planning programs. There are other models in the PG&E wildfire risk management ecosystem, such as the PSPS model, which are intended to inform operational risk mitigation using near-term data and forecasts.

Through modeled relationships between wildfire risk and an array of environmental and asset attributes, the WDRM helps mitigation program work planners understand why risk exists at a location or asset, and, therefore, which action(s) may be most effective for reducing the wildfire risk.

The WDRM estimates risk at geographic locations along the distribution network and for individual assets. Wildfire risk for the distribution network is determined from the results of two component models: the Probability of Ignition Model and the Wildfire Consequence Model.

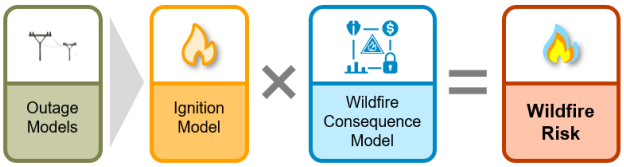

Figure 4 - Wildfire Risk Calculation

The Probability of Ignition, or p(i), Model uses two steps to predict the likelihood of an ignition for distribution grid assets and locations. First, a series of Probability of Outage, or p(o), models predict the likelihood of equipment asset outages that could be caused by various equipment and contact from object failure modes. Second, depending on an asset failure type and its failure mode, the likelihood that a failure will result in an ignition event is determined. The Probability of Ignition Model and the contributing Outage models are described in more detail in the *Distribution Network Event Probability Models v4 Documentation*.

The Wildfire Consequence (WFC) Model predicts the impact of an ignition event in terms of the potential hazard posed to life, property, and land. Consequence values are determined for the service territory based on simulated fire outcomes that use detailed fuels, weather, and topography data. Consequence values are generally higher at locations that are typically dry, windy, and have an abundance of burnable fuel. The WFC is described in more detail in the *Wildfire Fire Consequence Model v4 Documentation*.

The predictions from the Probability of Ignition Model and the Wildfire Consequence Model are combined to determine the Wildfire Risk for a distribution grid asset or location.

1.3 Mitigation Program Planning

The WDRM primary purpose is to inform various PG&E wildfire risk mitigation plans, also known as Work Plans. Work plans are produced, then executed, by various programs, including:

- *System Hardening* – replaces existing assets with more resilient equipment such as covered conductors or stronger poles or relocates assets to lower-risk locations.
- *Undergrounding* – moves existing assets underground to eliminate wildfire risk.
- *Vegetation Management* – performs expanded vegetation trimming and removal in selected locations.
- *Pole Replacement* – replaces old and worn wood distribution poles.
- *Transformer Replacement* – replaces old and overloaded distribution transformers.

The WDRM output is a relational dataset that can be viewed on spatial map with layered representation of risk, consequence, and probability values – each characterizing risk from different causes or assets. These layers of risk can be examined and compared individually, or they can be composited together to understand the full risk from all applicable distribution grid assets.

1.4 System Inspections and Electric Corrective Tags Programs

The WDRM, in addition to PG&E's long-term wildfire risk mitigation work plans, also inform the prioritization of annual work plans for both the System Inspections and Electric Corrective (EC) Tags Programs.

- *System Inspections* – develops a plan which emphasizing risk to determine assets to be inspected in the upcoming year and whether those assets will receive a ground or aerial inspection.
- *EC Tags Program* –addresses the Wildfire Mitigation Plan (WMP) annual commitment to meet annual risk reduction targets associated with the existing number of HFTD/HFRA tags.

1.5 Documentation Suite

This document is part of the documentation suite for the Wildfire Distribution Risk Model (WDRM) v4:

- WDRM v4 Documentation (this document)
- Wildfire Consequence Model v4 Documentation
- Distribution Network Event Probability Models v4 Documentation
- RaDA Algorithms and Methodologies

The intent of this document is to present the development, performance, and use of the Wildfire Distribution Risk Model. This document describes the calculation of distribution asset wildfire risk, aggregation of risk to System Hardening circuit segments, and the creation of risk composites in support of wildfire mitigation program planning.

Note that the calculation of wildfire risk is dependent on prediction results from the Distribution Event Probability and Wildfire Consequence models. These models are only generally described in this document. Detailed documentation for the Distribution Event Probability and Wildfire Consequence models can be found following the links provided above.

This document seeks to provide the lay reader with a broad understanding of WDRM v4. It is not intended to provide comprehensive detailed mathematical or scientific descriptions of all methods used to produce the risk model.

2 WDRM v4 Highlights and Evolution

The WDRM is continuously improved and expanded to incorporate refreshed data and new data sources, explore new event probability models that provide new causal path insights, and absorb advancements in wildfire simulation. The continuous improvement effort is reflected in the evolution of the WDRM version releases. While each new model has advanced the science of wildfire risk models they are each statistical approaches to characterizing and quantifying wildfire risk in support of PG&E's stand that catastrophic wildfire will stop. As statistical predictions the predictive power of the models or their subparts can have similar effectiveness while subsequent models can provide improvements in singling out specific risk drivers. For this reason, workplans developed with one version of the risk models do not become outdated or incorrect with the release of a new model.

2.1 WDRM v4 Highlights

WDRM v4 features several significant improvements to the modeling of wildfire risk.

- Concentrated effort to improve the quality of training and covariate datasets, which had a direct impact on the quality of model predictions.
- Migration of several equipment asset event probability models from spatial, pixel-based to asset-based, including:
  - Primary Conductors
  - Support Structures
  - Transformers
  - Voltage Regulators
- Development of new equipment asset-based event probability models, including:
  - Capacitor Banks
  - Dynamic Protective Devices
  - Fuses
  - Switches
- Vegetation event probability models were improved with data for:
  - Tree Canopy Density
  - Tree Health
  - Wind Direction
- Wildfire Consequence received several significant upgrades:
  - Technosylva's wildfire simulations were increased from 8-hour to 24-hour duration.
  - Technosylva's Terrain Difficulty Index (TDI) was incorporated into the Consequence model.
  - Dry Wind conditions were added to the Consequence model.
  - Egress and Suppression impacts are used to modify Consequence predictions.
- In response to System Hardening and Undergrounding mitigation work planning team requests, circuit segment aggregated risk rankings are produced based on wildfire risk per primary overhead conductor mile.

2.2 WDRM Version Evolution

Mitigating wildfire risk posed by utility assets is a rapidly evolving area of practice where improvements are achieved through the adoption of new data and methods. As such, PG&E's WDRM has evolved – and improved – over time.

Figure 5 provides an overview of the evolution and improvement of the Event Probability Models that contribute probability of failures and ignitions to the WDRM.

2.3 Legacy WDRM Models

Legacy WDRM version release data remain available for historical and audit purposes. WDRM v2 and v3 results are directly available to self-service users through the WDRM Landing Page in Foundry.

2.3.1 WDRM v1

WDRM v1 was generated for the 2017 initial RAMP filing under the S-MAP agreement. The first-generation RAMP model for Enterprise Risk Management used probabilistic modeling. It was built in an Excel format (with an add-in feature called @Risk) and relied on Monte Carlo simulation to produce a baseline and mitigated Multi Attribute Risk Score (MARS) and Risk Spend Efficiency (RSE). The first version of the model used in the 2019 WMP predicted wildfire risk on a per-circuit basis and circuit segment basis, for High Fire Threat District (HFTD) only.

In 2019, PG&E started to prioritize circuits and circuit segments for wildfire risk mitigation using a probability of ignition from this v1 model, and wildfire consequence predictions from fire modeling software vendor REAX. Mitigation work planned with the benefit of the v1 WDRM was performed during 2019, 2020, and 2021.

2.3.2 WDRM v2

WDRM v2 was generated for the 2020-2021 second RAMP filing in accordance with the S-MAP Settlement Agreement (Dec 2018). WDRM v2 took a meaningful step forward by using more advanced modeling. WDRM v2 featured more specific event models for predicting ignitions and used PG&E's version of the CPUC's multi-attribute value function (MAVf) to estimate wildfire consequences as required by the S-MAP Settlement Agreement. During the second year of the filing, the v2 model was improved to use more advanced algorithms and machine learning.

PG&E also improved the v2 modeling to be more granular spatially and by risk driver. The spatial resolution of the model was improved from circuits for v1 to 100m x 100m geographic areas, or pixels, within HFTD for v2. In addition, vegetation-caused ignitions were modeled separately from other ignitions along conductor lines to understand the differences between these two risk drivers. This resulted in two related but separate models, vegetation-caused and conductor-involved, which were subsequently used by the EVM and System Hardening wildfire risk mitigation programs, respectively.

WDRM v2 also featured upgraded wildfire consequence mapped into MAVF fire size/severity tranches based upon physics-based fire simulations provided by outside vendor Technosylva.

2.3.3 WDRM v3

WDRM v3 was released in support of the 2023 WMP. The third generation of WDRM development was guided by internal reviews, public safety specialist feedback, technology partner feedback, third-party intervener comments, and an independent third-party model review.

WDRM v3 greatly expanded the scope of the model and included more-advanced machine-learning modeling techniques, incorporated newly available data, and significantly expanded its understanding of potential ignition sources from distribution assets.

WDRM v3 modeled several new causal pathways to ignitions. While WDRM v2 provided ignition event modeling for primary conductors and vegetation, WDRM v3 offered asset event models for secondary conductors, support structures, transformers, and voltage controls. New contact from object event models were added for animal and third-party contacts with distribution assets.

WDRM v3 incorporated Wildfire Consequence v3.4, which included updates to consider 2030 forecasted growth for fuels, Fire Potential Index, simulated flame length, and simulated flame rate-of-spread to predict ignition consequences.

3 WDRM v4 Risk Prediction

3.1 Risk Model Overview

There are two main component models for determining risk in the WDRM, an event probability of ignition and the consequence of ignition at a geographic location. However, both the event probability of ignition and the consequence models are composed of supporting models that contribute causal knowledge to the WDRM. *Figure 7* provides an overview of all model components that contribute to the estimation of wildfire risk.

Probability of ignition, or p(i), sometimes referred to as Likelihood of a Risk Event (LoRE), represents the expected count of ignition events for an annual wildfire season of June 1st through November 30th. The probability of ignition is determined from a suite of distribution event probability models. All but one of the event probability models are probability of outage (or failure) models. These models predict the expected number of outages or failures for a fire season for a specific type of asset found in the distribution network. The outcomes for the outage event models are in turn processed through a single probability of ignition given outage (p(i|o)) model that yields the probability of ignition values for all event models. Full documentation on the probability of ignition model and the associated set probability of outage models is available in a separate document, *Distribution Network Event Probability Models (DEPM) v4 Documentation*.

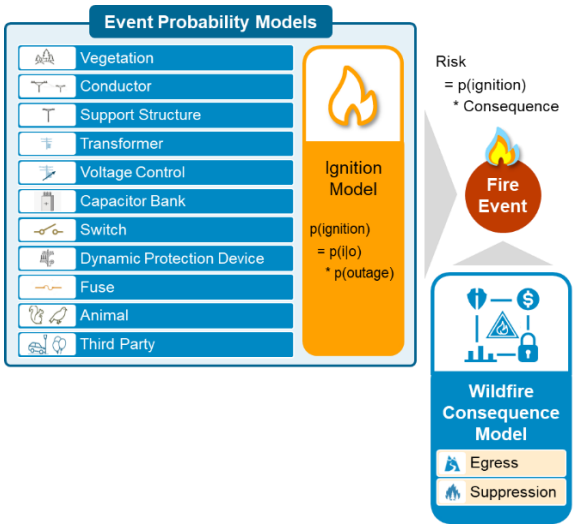

Figure 7 – WDRM Risk Components

Consequence of an ignition event, sometimes referred to as Consequence of a Risk Event (CoRE), provides the expected severity of wildfire outcome for a specific geographical location within the distribution network. Full documentation on the Consequence model is available in a separate document, *Wildfire Fire Consequence Model (WFC) v4 Documentation*.

The combination of probability of ignition and its consequence results in a relative wildfire risk value that can be used to inform wildfire mitigation planning. This document explains how wildfire risk is determined from combining probability of ignition and consequence values for assets, locations, and circuit segments, and mitigation program composites.

3.1.1 Risk Value Calculation

Wildfire Risk for a given asset or asset location is simply the product of an event probability of an ignition and the expected consequence of an ignition event. The event probability of ignition has two modeling components, an event probability of outage and the probability of ignition given outage. *Figure 8* illustrates the wildfire risk calculation form its components.

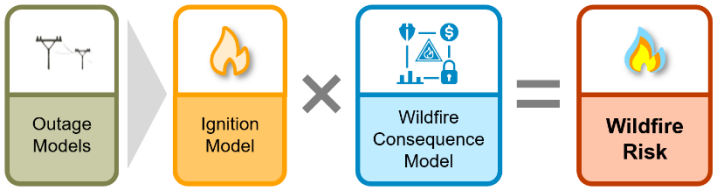

Figure 8 - Wildfire Risk Calculation

In its simplest form, wildfire risk is the product of an event probability of ignition and its potential consequence:

$$Risk = p(i) * Consequence$$

The probability of ignition, however, is itself the product of an event model probability of outage and the estimated probability of ignition given an outage, and the risk calculation can be expanded to:

$$Risk = p(o) * p(i|o) * Consequence$$

Where:

Variable	Description
Risk	Seasonal wildfire risk for an asset or asset location
p(i)	Seasonal probability of ignition for an asset or asset location
p(o)	Seasonal probability of outage (or failure) for an asset or asset location
p(i|o)	Seasonal probability of ignition given probability of outage
Consequence	Expected wildfire consequence for an ignition location

In theory, the WDRM calculates a wildfire risk value for every asset and every location containing an asset for the entire distribution network. Unfortunately, data quality issues and the asynchronous nature of many of the underlying data sources will result in some WDRM assets and locations having insufficient information to generate an event probability of ignition, an ignition consequence value, or both. As a result, the WDRM is always missing some wildfire risk values for a small number of assets and locations.

3.1.2 Key Modeling Constructs

There are several important modeling constructs for delivering the WDRM risk data. WDRM risk is the result of combining probability of ignition predictions from the Event Probability Models with the probable wildfire outcome from the Wildfire Consequence Model. However, the supporting models provide their data at the granularity of either an individual asset or an individual geospatial grid pixel. For the risk data to be useful for mitigation work planning, the risk data must be adapted to match how the work is planned. This is accomplished through two methods of processing: results aggregation and multi-model compositing. Results aggregation organizes and sums multiple pixel and asset risks to the work planning context of circuit segments used by several mitigation programs. Multi-model compositing combines the risk from several different event models to create a total risk value for work plan prioritization.

3.1.2.1 Modeling Components

A persistent goal for each new WDRM version release is to improve its predictive power over its predecessor. One way this has been achieved is to increase causal specificity of the Event Probability and Wildfire Consequence Models.

For the Event Probability Models, WDRM v2 only delivered separate event probability models for System Hardening and Vegetation Management mitigation work planning. For WDRM v3, 17 unique causal event probability models were developed. WDRM v4, via DEPM v4, delivers 23 causal event models.

There are two types of Event Probability model, Equipment Asset Models and Contact From Object Models. Asset Models provide event probability values for specific equipment assets, while Contact From Object Models are geo-spatial, delivering probability values associated with 100m by 100m grid of pixels that overlay the distribution assets.

DEPM v4 delivers fourteen Equipment Asset and nine Contact From Object models for WDRM v4 risk calculations.

The Wildfire Consequence Model v4 that supports WDRM v4 has also grown in capability and now includes two impact adjustments for Egress response and fire Suppression.

3.1.2.2 Results Aggregation

Several use cases for the WDRM results require understanding the total or average risk for a set of assets. This is accomplished through the aggregation of contributing causal risks. The WDRM supports the aggregation of risk to circuit segments, which break up distribution circuits into small sections which are more appropriate for planning by mitigation programs such as System Hardening, Undergrounding, and Vegetation Management. For each circuit segment, the risk for any given event probability model can be summed to determine the aggregated risk contribution. In the case of an Asset model, the risk for each asset assigned to a circuit segment is summed. For a Contact From Object model, the risk value for each pixel touched by the circuit segment is summed. Risk aggregation is explained in more detail in Section *4.1*.

3.1.2.3 Model Compositing

Some mitigation programs need to consider the combined risks from multiple causal Event Probability Models. The WDRM provides this capability through the compositing of risk. WDRM v4 provides several model composites for assets that have multiple causal models and for specific mitigation work plans.

Asset model composites sum the constituent causal models to provide a summed risk. For instance, the Primary Conductor Line Slap, Wire Down, and Other causal model risk are combined to produce a total Primary Conductor risk.

Mitigation program composites sum risks from the suite of causal models that can influence the selection of risk mitigation methods. WDRM v4 provides composite risk values in support of System Hardening, Undergrounding, and Vegetation Management mitigation work planning.

Model compositing is explained in more detail in Section *4.2*.

3.2 Model Development Process

All WDRM models are developed following an iterative process. A high-level view of the development process is shown in *Figure 9*.

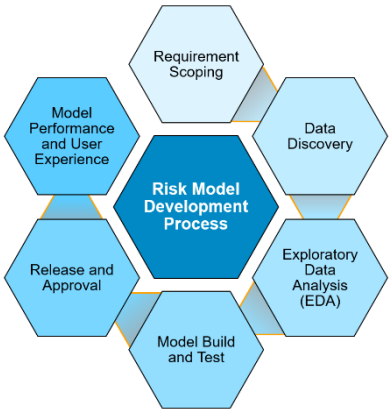

Figure 9 - Model Development Process

Requirement Scoping – Encompasses user feedback, new user requirements, potential performance improvements, and new or desired causal information to set model development goals.

Data Discovery – Researching new data sources, obtaining updates to refresh existing data sources, and cleaning and validating data for potential model use.

Exploratory Data Analysis (EDA) – Data analysis and investigation to determine fitness for modeling.

Model Build and Test – Successive builds of proposed models verified for performance against independent testing data.

Release and Approval – Candidate release models are published to the user community for critique. Viable release candidates are presented through a governance process to gain approval for general release in support of wildfire mitigation work planning.

Model Performance and User Experience – The approved model is monitored for performance against actual events and user feedback is collected to inform the next iteration of model development.

This is a very simplified description of the risk modeling process. At any step in development, knowledge gained can require an iteration back to an earlier process step or even to a reevaluation of model development scope.

3.3 Event Probability Models Contribution

The Event Probability Models support the WDRM by predicting where distribution assets are most likely to experience an abnormal operating event that results in an outage or ignition event and include:

- Probability of Outage Models
  - Equipment Asset Models
  - Contact From Object Models
- Probability of Ignition (given Outage) Model

Equipment Asset Models consider event history and contributing factors to predict failure of specific types of electrical equipment. Each asset model uses a unique set of inputs (covariates) from a pool of asset attributes and environmental conditions. For some assets, unique models (sub-sets), are produced for specific types of failures.

The following Equipment Asset models were produced in support of WDRM v4:

- Capacitor Bank
- Dynamic Protection Device (DPD)
- Fuse
- Primary Conductor
  - Line Slap
  - Wire Down
  - Other
- Secondary Conductor
- Support Structure
  - Electrical Failure
  - Structural Failure
- Switch
- Transformer
  - Leaking
  - Failure
- Voltage Regulator
- Other Equipment

Contact from Object Models consider event history and contributing factors to predict failure caused by contact from foreign objects with electrical assets. Each contact model uses a unique set of inputs (covariates) from a pool of object attributes and environmental conditions. All contact models provide unique models (sub-sets) for specific types of contact failures.

The following Contact from Object models were developed in support of WDRM v4:

- Animal
  - Bird
  - Squirrel
  - Other
- Third Party
  - Balloon
  - Vehicle
  - Other
- Vegetation
  - Branch
  - Trunk
  - Other

The Probability of Ignition is the likelihood that an asset-based ignition will occur during a fire season. Probability of Ignition is predicted by the Probability of Ignition Given Outage Model using the probability of outage predictions from all of the Asset Equipment and Contact From Object Models along with other attributes such as environmental conditions. Fire season probabilities of ignitions are individually predicted for each specific Asset Equipment and Contact From Object Model.

3.4 Wildfire Consequence Model Contribution

The Wildfire Consequence Model supports the WDRM by estimating the likely outcome of an ignition originating at the geographical location of any electrical asset. The consequence model is trained to historical fires while considering Technosylva fire simulations, PG&E Meteorology's FPI index, dry wind conditions, and other fuel and weather conditions. In addition, the consequence estimates are adjusted for population Egress and fire-fighting Suppression impacts.

The consequence model produces estimates outcomes for acres burned, buildings damaged, and probable fatalities. The model outcomes are transformed through a Multi-Attribute Value function (MAVf) provided by Enterprise Risk Management to determine the final consequence value used for calculating wildfire risk.

The Wildfire Consequence Model v4 that supports WDRM v4 risk has also grown in capability when compared with Wildfire Consequence Model v3.4, and now includes two impact adjustments for Egress response and fire Suppression as shown in *Figure 10*.

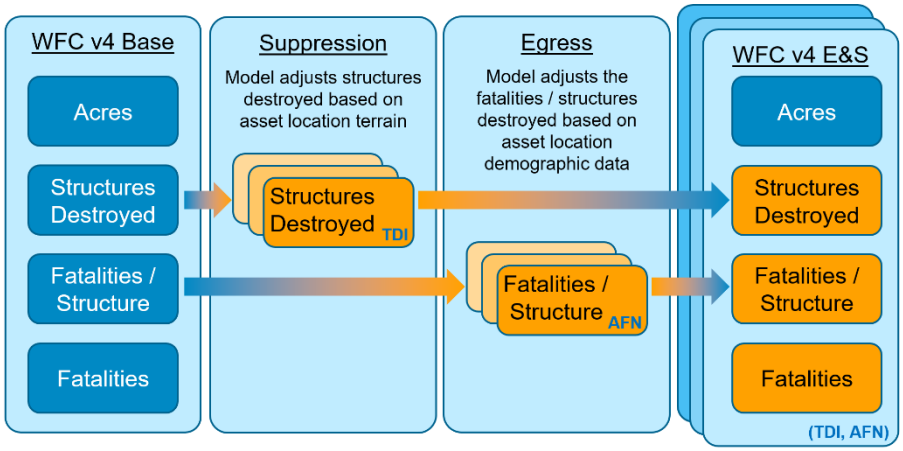

Figure 10 - Wildfire Consequence Model v4

4 Compositing and Aggregation

An important objective for the WDRM is to provide wildfire risk analysis in support of wildfire risk mitigation program planning, including System Hardening, Undergrounding, and Vegetation Management. Mitigation program planners need to understand model results in a larger context than the direct model outputs. Providing contextual values requires that the asset and spatial model results be composited and aggregated to the desired planning context. The WDRM, based on requirements originally provided by the System Hardening program, provides risk results that composite several of the event probability model risk results and aggregate these risks to circuit segments.

Detailed descriptions on circuit segment definitions, risk compositing, and risk aggregation can be found in the RaDA Algorithms and Methodologies documentation.

4.1 Model Results Aggregation

The WDRM is supported by Event Probability models that produce both equipment asset and geospatial results. Equipment Asset models produce results that estimate event probabilities or risk for individual assets at point locations. Spatial, or grid pixel, models, product results that estimate event probabilities or risk within 100m by 100m square pixels that form a grid over the distribution and transmission service territories. The Wildfire Consequence model also produces geospatial results assigned to the same 100m by 100m pixel grid. Assigning risk to a circuit segment context requires the aggregation of multiple grid pixel and equipment asset risk results.

4.1.1 Aggregation Methodology

Simply, circuit segment aggregation sums up all the potential risk that modeled along the length of a segment. *Figure 11* shows an example of two circuit segments that intersect multiple grid pixels and have multiple assigned equipment assets ( ). For geospatial models, this pixel risk for any pixel that is intersected by a circuit segment is summed to determine the aggregated pixel risk. For asset models, the risk for each asset belonging to the circuit segment is summed to determine the aggregated asset risk. Finally, the summed pixel and asset risks can in turn be summed to calculate the total aggregated circuit segment risk.

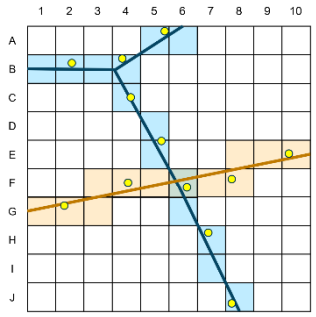

Figure 11 - Circuit Segment Aggregation

Shared pixels and assets complicate circuit segment aggregation of risk. In *Figure 11* the two circuit segments share a common pixel, F6, and a support structure (pole) asset also located in pixel F6. To keep the total sum of risk on the network constant, these shared risk results must be partially distributed to each of the circuit segments. The aggregation methodology, in this case, would assign half of the F6 pixel risk and half of the support structure risk to each of the circuit segments.

Aggregation methodology is described in more detail in RaDA Algorithms and Methodologies documentation.

4.2 Compositing Event Models

Ultimately, the purpose for the WDRM is to inform the prioritization of wildfire risk mitigation programs. The WDRM event probability model risk results can be flexibly composited to provide risk values and priority rankings for specific mitigation programs. Using composited results, programs can prioritize mitigation of the highest total risks while using the contributing event probability models to understand the best mediation approach to handle the specific components of risk.

Risk can be composited for any combination event probability models. Mitigation planners and Subject Matter Experts can focus on the drivers of risk for which they are responsible with confidence that their composited view is relevant to their work planning needs.

4.2.1 Compositing Methodology

An event probability model produces, by asset or pixel, a probability of ignition. Combining a probability of ignition with its consequence produces the wildfire risk. Probability of ignition and risk results can be composited to create total probability of ignition and total risk. As visualized in *Figure 12*, individual model results are summed to determine total composite results.

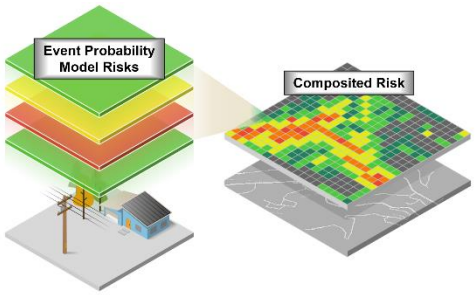

Figure 12 - Model Compositing

Compositing methodology is described in more detail in RaDA Algorithms and Methodologies documentation.

4.2.2 Mitigation Composites

Mitigation program work planners are often interested in a partial set of event probability model risk results. Custom composites are configured so that the total risk for only the applicable event models gets considered as part of the work prioritization process. *Figure 13* illustrates how model selection can be used to configure a composite for a specific work plan.

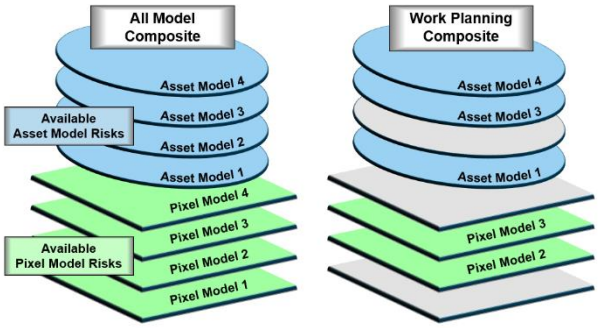

Figure 13 - Mitigation Composite Membership

WDRM v4 delivers the following mitigation composites, composed from the 23 available event probability models:

Table 1 – WDRM v4 Mitigation Composites

4.3 Composite Aggregation

Composites are defined in support of a specific mitigation program. As mentioned previously, many mitigation programs are aggregates of risk results, most commonly the context of circuit segments. Aggregating composite results require a specific calculation procedure.

4.3.1 Aggregated Composite Probability of Ignition and Risk

The aggregation of event probability of ignition and risk composites is relatively straightforward as they are simply sums of all component results. *Figure 14* provides a simple example where a circuit segment is comprised of several assets located in two consequence pixels. The composited results for the assets ( ) are shown beneath the consequence grid pixels. The aggregation of the composited values for probability of ignition and wildfire risk are shown in the blue-shaded boxes to the lower right.

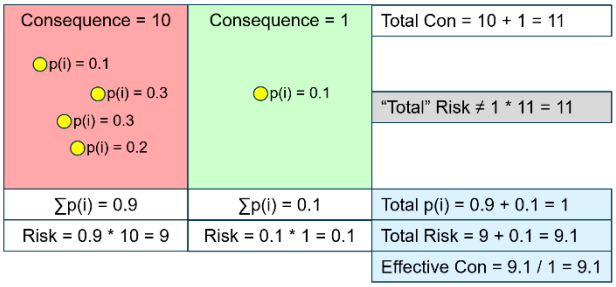

Figure 14 - Composite Aggregation Example

4.3.2 Aggregated Composite Ignition-Weighted Consequence

Unfortunately, consequence values cannot be directly composited like probability of ignition and wildfire risk when aggregating contextually to circuit segments. This is because the process of compositing and circuit segment aggregation will combine each consequence pixel result with a varying number of event probability of ignition results. Referring again to *Figure 14*, we can see in the gray-shaded box that using a simple sum of the consequence values and the total probability of ignition will not yield the correct total risk.

The resolution to this mathematical inconsistency is to back-calculate the effective, or ignition-weighted, consequence for an aggregated composite by dividing the total aggregated risk by the total aggregated probability of ignition. This calculation is shown in the blue-shaded box at the lower right-hand corner of the example.

5 Results and Model Performance

WDRM v4 benefited from improvements to both the Event Probability Models for outages and ignitions and the Wildfire Consequence Model. As a result of the many contributing model improvements, WDRM v4 produces risk values that show a general flattening of the risk profile for the service territory.

5.1 WDRM v4 Performance

WDRM wildfire risk is calculated using predicted values from the supporting Event Probability and Wildfire Consequence models. Therefore, WDRM performance is dependent on the performance of the supporting models. Significant performance improvements were realized for WDRM v4 from both supporting models.

A focused effort was made to improve the quality of the event probability datasets. Historical event records were reviewed to correctly attribute failures and ignitions to their correct cause and equipment asset relationships were improved so that risk could be determined and aggregated appropriately. In addition, both the failures and ignitions datasets were corrected for probable impacts of EPSS activation.

Several new event probability models were introduced for v4, including Fuses, Switches, and Voltage Regulators as well as introducing three Primary Conductor causal models for Line Slap, Wire Down, and Other. Also introduced for v4 were Asset-based models. New models were developed as Asset-based, while v3 pixel-based spatial models for Capacitor Banks, DPD, Primary Conductors, Support Structures, and Transformers were transitions to Asset-based. These changes contributed to improved model performance for both probability of outage and probability of ignition predictions.

Figure 15 provides an overview of Event Probability Model v4 performance. Performance values shaded in green show strong performance, in tan demonstrate adequate performance, and a few, shown in gray, exhibit poor performance.

Event Model	p(o) AUC	p(i) AUC	p(o) Conc. Factor	p(i) Conc. Factor
Animal – Bird	0.651	0.683	1.79	2.16
Animal – Squirrel	0.839	0.852	3.70	3.91
Animal - Other	0.741	0.756	2.53	2.93
Capacitor Bank	0.558	0.549	1.40	1.40
DPD	0.625	0.475	1.00	1.50
Fuse	0.669	0.681	2.00	2.10
Primary Conductor – Line Slap	0.770	0.757	3.33	3.33
Primary Conductor – Wire Down	0.628	0.639	1.91	1.78
Primary Conductor - Other	0.694	0.706	2.75	2.50
Secondary Conductor	0.718	0.728	2.49	2.59

Figure 15 - Event Probability v4 Model Performance

More details on Event Probability Model v4 performance can be found in Distribution Network Event Probability Models v4 Documentation.

The Wildfire Consequence Model v4 achieved performance improvements from several initiatives. Fire simulation times were increased from 8 to 24-hours, historical fire datasets were reviewed and cleaned to increase number of fires used of model calibration, a Dry Wind Conditions index was developed, Technosylva's Terrain Difficulty Index was incorporated, and public Egress and fire Suppression impacts adjustments were added to the v4 model.

The many model updates contributed to better performance for all three model outputs as shown in *Figure 16*. In each case the v4 model high consequence areas account better for historical fires.

More details on Event Probability Model v4 performance can be found in Wildfire Consequence Model v4 Documentation.

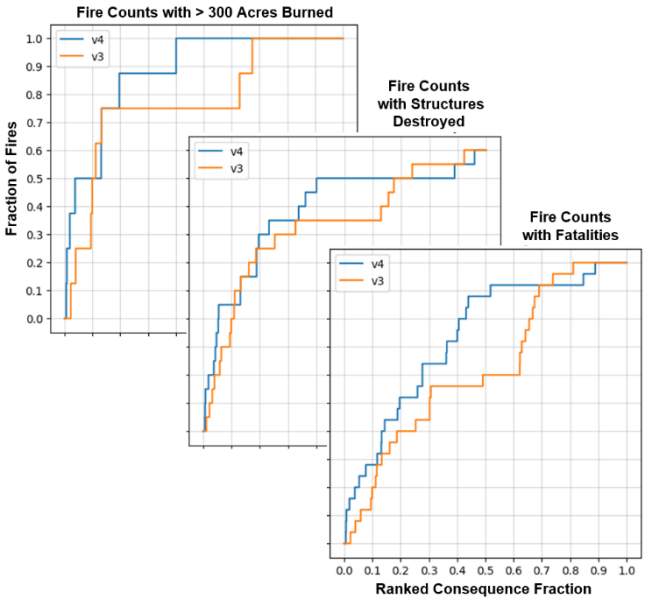

Figure 16 - Wildfire Consequence v4 Performance

5.2 WDRM v3/v4 Comparison

The most significant discovery when comparing WDRM v4 with its predecessor v3 is that wildfire risk is more widely distributed across the distribution grid than previously thought. This is most easily understood from a comparison of the v3 and v4 risk buydown curve as shown in *Figure 17*.

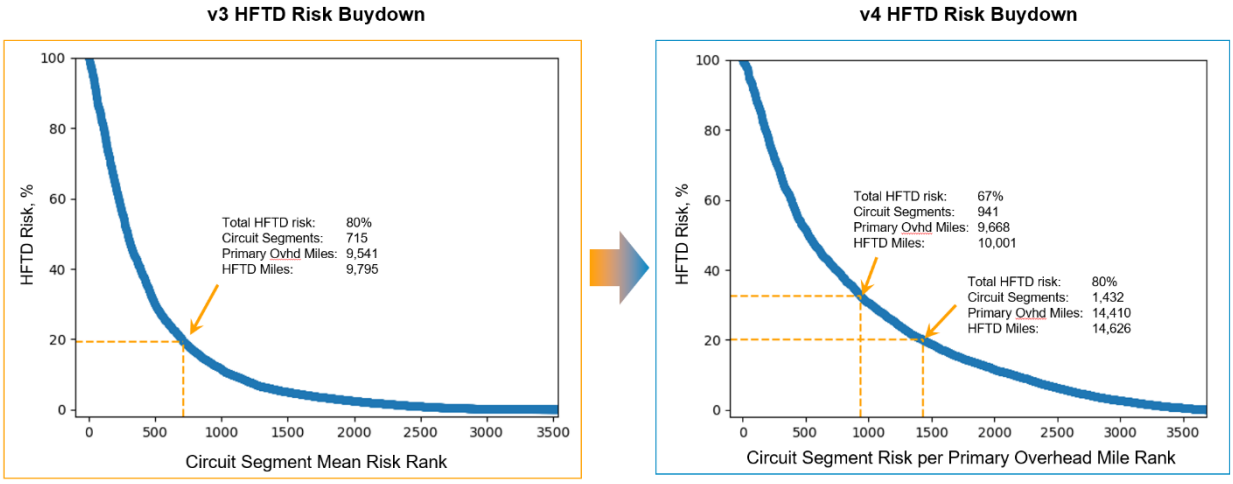

Figure 17- WDRM v3/v4 Risk Buydown Curves

The WDRM v4 risk buydown curve is noticeably flatter, and critically, increases the amount of primary overhead conductor length that represents 80% of the HFTD wildfire risk from 10,000 to 14,400 miles. While the flattened v4 risk buydown curve has multiple sources in the updated models, the most pronounced effect from is the Wildfire Consequence Model. Consequence results were likewise flattened when comparing v4 with v3.4, in large part due to the addition of public Egress and fire Suppression impacts.

Another way to visualize the redistribution of wildfire risk in WDRM v4 is to look at relative county risk aggregations as shown in *Figure 18*. For WDRM v3, El Dorado County dominated the concentration of risk for the distribution grid. WDRM v4 shows a more even distribution of risk. While El Dorado County still has the highest concentration of risk for v4, several other counties are similar in risk. Particularly notable is the increase in relative percent of aggregated risk for Sonoma and Fresno counties as detailed in *Figure 19*.

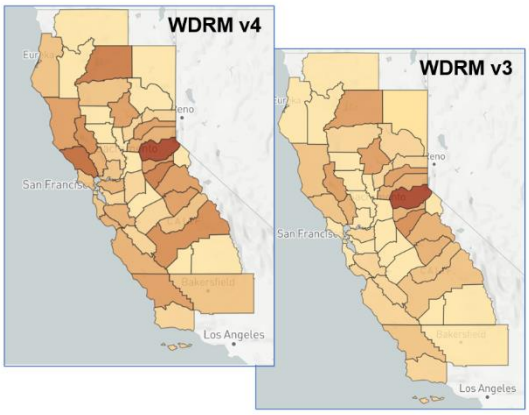

Figure 18 - WDRM v3/v4 Relative County Risk Aggregations

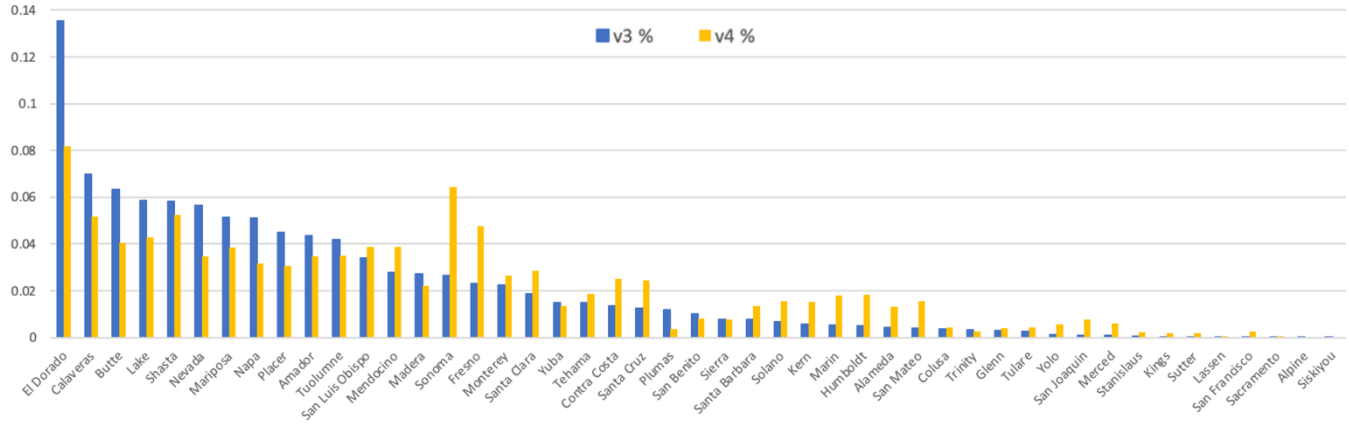

Figure 19- WDRM v3/v4 Relative County Risk Distribution

Finally, the System Hardening maps implemented in Foundry provide a more detailed look at how circuit segment relative risk values have changed from WDRM v3 to v4.

Figure 20 is the relative risk map for WDRM v3 emphasizing the circuit segments that are in the top 30% in terms of risk rank, with the top 1% of ranked circuit segments shown in red. Circuit segments outside the top 30% of risk rank are shown in a dark blue.

For WDRM v3, the western Sierras had a very high concentration of top 1% risk.

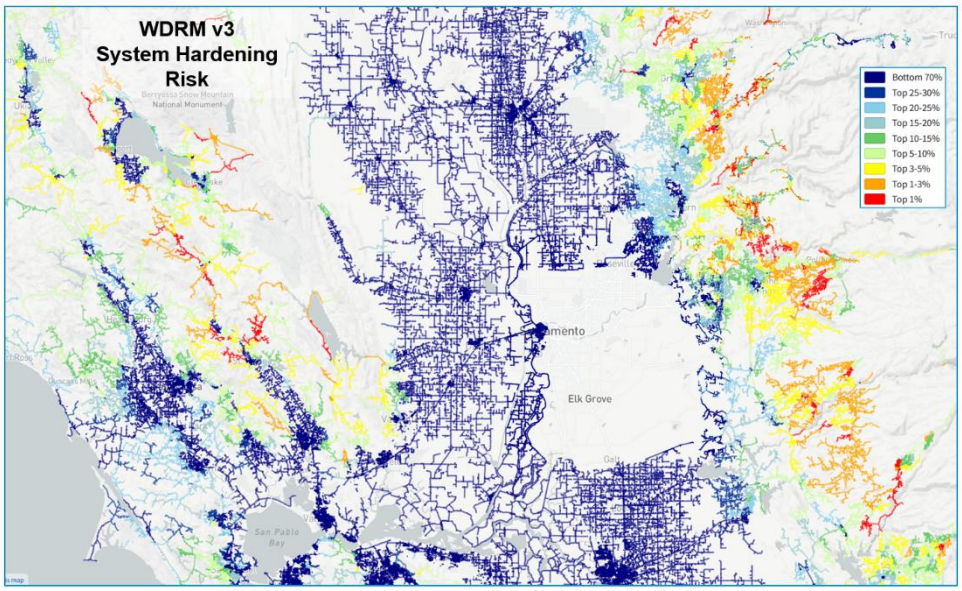

Figure 20 - WDRM v3 System Hardening Risk Map

As described previously, WDRM v4 produces a flatter risk curve and shifts relative areas of risk when compared with v3. *Figure 21* is a heat map of relative risk change between WDRM v3 and v4 where dark red indicates the relative risk increased and dark blue highlights where the relative risk decreased for the transition from WDRM v3 to v4.

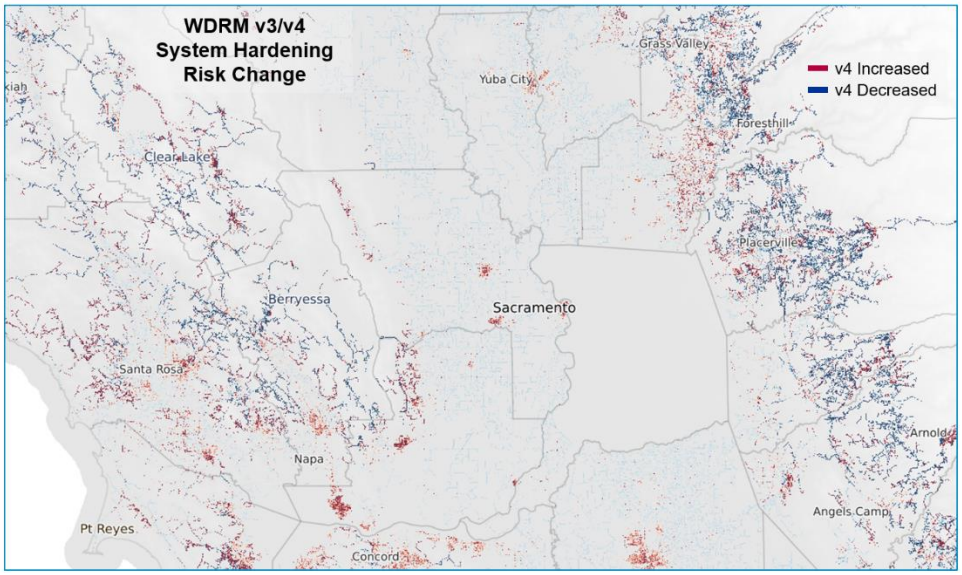

Figure 21 - WDRM v3/v4 Relative Risk Change Map

Figure 22 presents the WDRM v4 relative risk map, again emphasizing the top 30% of circuit segments by relative risk rank.

A visual comparison with the WDRM v3 map confirms that WDRM v4 projects lower relative risk for the western Sierras while elevating relative risk for the coastal mountains. The shift in relative risk between WDRM v3 and v4 contributes to the general flattening of the risk buydown curve.

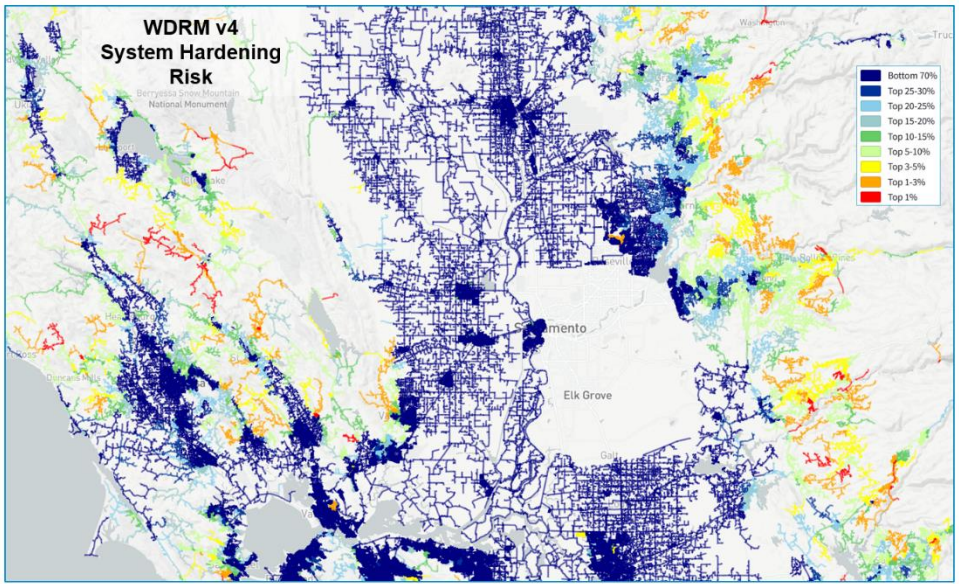

Figure 22 - WDRM v4 System Hardening Risk Map

5.3 Validation Reviews

WDRM v4 went through several formal and informal reviews during development. The critical model reviews were with PG&E's Wildfire Risk Governance Steering Committee and an external review performed by third-party Energy and Environmental Economics, Inc. (E3).

5.3.1 Wildfire Risk Governance Steering Committee Review

Several review meetings were held with the Wildfire Risk Governance Steering Committee during the development of WDRM v4. Three specific areas of WDRM v4 development were in response to action items from the 2023 Wildfire Mitigation Plan (WMP). Each WMP action item was reviewed with the committee to inform and obtain agreement to implement planned development in WDRM v4. Inform review meetings were also held for the Wildfire Consequence Model v4 and WDRM v4 Release Candidate 3 (RC3). Finally, WDRM v4 RC4 was approved as WDRM v4 at an approval meeting held on January 11th, 2024.

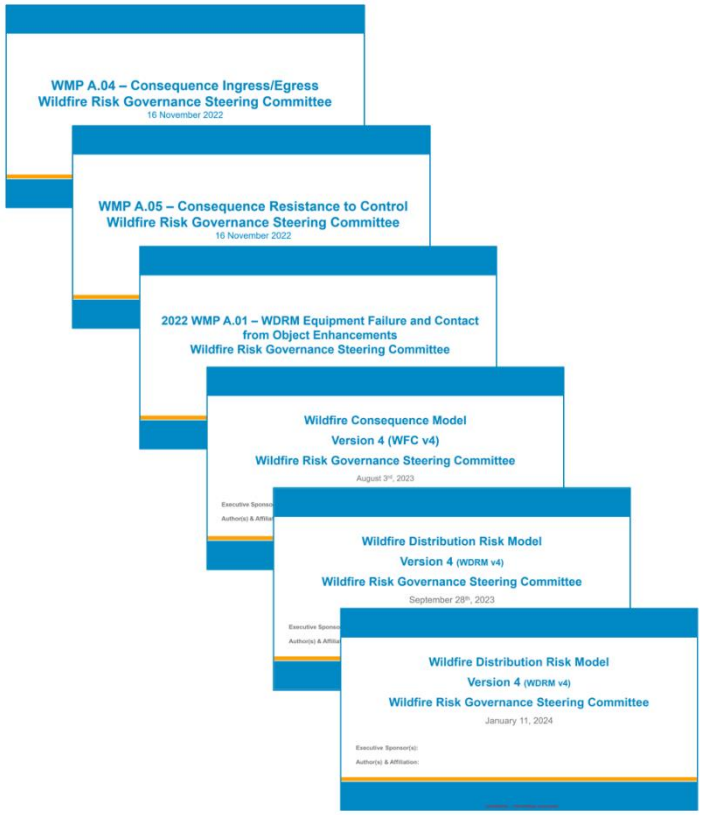

Figure 23 - WRGSC Review Meetings

5.3.2 Energy and Environmental Economics, Inc. (E3) Review

An independent, third-party review of the WDRM v4 was conducted by E3 to evaluate the following objectives:

- Review the suitability and applications of consequence data in the modelling framework.
- Review the specific use of the risk model information in each of its operations areas.
- Describe potential future uses of v4 and longer-term multi-year wildfire planning models.

A few comments from the E3 review:

> *"As with in our previous reviews, overall we have seen considerable improvement between versions of the PG&E wildfire risk modeling effort."*
>
> *"Over the last several years, PG&E has continued to improve upon their wildfire risk modeling framework and has built a suite of models that is capable of systematically quantifying the wildfire risk across their system, frequently going above and beyond requirements."*

"PG&E should continue development of the model to inform the entire risk planning decision space, building on v4 to produce transparent and justifiable company-wide mitigation budgets for short- and long-term planning. While we continue to believe that the combination of informed risk modeling and experienced SME's provides a robust risk management framework, we also believe that the models, as they become more informative, should have an increasing role in the decision-making process."

E3 identified several potential improvements for future versions of the WDRM:

"*Our findings from this review are based on documentation provided by PG&E on their v4 model, interviews with PG&E's risk modeling team, and interviews with experts comprising the external technical advisory committee assembled by E3. The following bullets re-state the most pertinent recommendations stemming from our present review:*

- *PG&E should focus on using its model to develop transparent and justifiable company-wide mitigation budgets.*
- *Given the unique nature of wildfire risk and mitigations, consideration should be given to cost recovery mechanisms outside of the traditional general rate case.*
- *Development efforts should be right-sized based on impact.*
- *PG&E should seek to improve and justify simplifications made in the consequence model.*
- *Uncertainty should be incorporated into modeling outputs to stabilize results.*
- *PG&E should consider incorporating air quality and health impacts."*

6 WDRM Future Plans

PG&E has historically produced the WDRM on an annual cycle. In the future, WDRM releases will be aligned with the WMP filing schedule. Therefore, this version of the WDRM is planned in support of the 2026 WMP. The RaDA team 3-year risk modeling product plan is shown in *Figure 24* with WDRM plans highlighted in blue font.

WDRM v4 delivered several features planned for 2024/2025 development. Additional features will be delivered during the remainder of 2024 and 2025. Substantial efforts are also expected to further improve the capture, detail, maintenance, and curation of data sets used for risk models. Future risk modeling will progress beyond informing mitigation work plan development and expects to provide risk and risk reduction values in support of data driven portfolio level decisions for the Integrated Grid Planning process.

Figure 24 - RaDA Product Plan - WDRM

The product plan for the Event Probability Models that contribute to the WDRM calls for the development of new risk driver causal models to improve predictive performance and provide more selectivity for mitigation work plans. In response to our user community needs to compare and balance investments across multiple risks, the Event Probability Models will be expanded beyond its current annual fire season focus to predict failures, outages, and ignitions for the full calendar year.

The Wildfire Consequence Model will continue to evolve, refining the Egress and Suppression impacts delivered for v4 and developing new impact features for vulnerable communities, conflagration, and fire consequence in the Wildland Urban Interface (WUI).

Wildfire Bow Tie Toy Problem

Wildfire Bow Tie Model Toy Problem

*Description: This analysis presents the toy problem of wildfire risk bow tie, focusing on **distribution overhead destructive fire risk**.*
- *The low, medium, and high cases are based on the lower bound, point estimate, and upper bound of the **50%** confidence interval (CI), respectively, for each key input:*
  1) Ignition Frequency — stratified by HFTD/HFRA designation
  2) Probability of Red Flag Warning (RFW) given an ignition, Prob(RFW|Ignition), — stratified by HFTD/HFRA designation
  3) Probability of an ignition burning greater than 300 acres, Prob(>300 acres|Ignition), — stratified by HFTD/HFRA and RFW designations
  4) Probability of a greater-than-300-acres fire becoming destructive, Prob(Destructive|>300 acres), — stratified by HFTD/HFRA and RFW designations
  5) Shape and scale parameters of truncated Pareto II distribution for financial consequence.
- *The resulting destructive fire risk estimates range from approximately 0.5x to 2x the medium-case estimate.*
- *The point estimate of non-destructive fire risk is subsequently added to derive the final risk range. Because non-destructive fires contribute only ~1% of total risk, incorporating uncertainty for this component would have negligible impact on the overall range.*

UNIT COST METHODOLOGY

Workpaper 030
Pacific Gas and Electric Company
Electrical Undergrounding Program
Unit Cost Methodology

Background	Table 1 presents PG&E's calculation of the proposed unit cost values included in the EUP Target/Timeline Table. The table illustrates how PG&E developed its unit cost forecast by incorporating resource allocation assumptions (i.e., sourcing strategies), unit cost improvement assumptions (i.e., work execution strategies), and escalation rates applicable to each resource type.

Table 1. Unit Cost Calculation Table by Resource Type

Year	Unit Costs Included in PG&E's EUP Target/Timeline Table		Resource Type								
			Lump Sum			Internal			Unit Pricing		
	Unit Cost Unescalated[d]	Unit Cost Escalated[c]	Resource Allocation[a]	Unit Cost w/ Improvements (Unescalated)[b,d]	Unit Cost w/ Improvements (Escalated)[b,c]	Resource Allocation[a]	Unit Cost w/ Improvements (Unescalated)[b,d,e]	Unit Cost w/ Improvements (Escalated)[b,c,e]	Resource Allocation[a]	Unit Cost w/ Improvements (Unescalated)[b,d]	Unit Cost w/ Improvements (Escalated)[b,c]
2025		$3.11	25%	$2.92	$2.92	15%	$3.45	$3.45	60%	$3.10	$3.10
2026		$3.25	25%	$3.05	$3.05	15%	$3.61	$3.61	60%	$3.24	$3.24
2027		$3.03	25%	$2.84	$2.84	15%	$3.39	$3.39	60%	$3.02	$3.02
2028	$3.05	$3.05	25%	$2.85	$2.85	15%	$3.45	$3.45	60%	$3.03	$3.03
2029	$3.03	$3.10	30%	$2.84	$2.91	13%	$3.44	$3.55	57%	$3.03	$3.10
2030	$3.00	$3.14	37%	$2.84	$2.96	12%	$3.43	$3.65	51%	$3.02	$3.15
2031	$2.98	$3.18	43%	$2.83	$3.01	11%	$3.42	$3.75	46%	$3.01	$3.21
2032	$2.96	$3.23	49%	$2.82	$3.07	11%	$3.41	$3.86	40%	$3.00	$3.26
2033	$2.95	$3.30	53%	$2.82	$3.13	12%	$3.40	$3.97	35%	$3.00	$3.33
2034	$2.94	$3.36	58%	$2.81	$3.19	13%	$3.40	$4.09	29%	$2.99	$3.39
2035	$2.92	$3.42	63%	$2.80	$3.25	13%	$3.39	$4.21	24%	$2.98	$3.45
2036	$2.91	$3.49	68%	$2.79	$3.31	14%	$3.38	$4.33	18%	$2.97	$3.52
2037	$2.90	$3.56	72%	$2.79	$3.37	15%	$3.37	$4.45	13%	$2.96	$3.59

Assumptions

[a]Resource Allocation

The annual percentage of the proposed EUP annual mileage targets assumed to be allocated to each resource type (e.g., Lump Sum, Unit Price, Internal). See PG&E's EUP Chapter 5, Section 3.c.1 *"Sourcing Strategies to Reduce Program Costs"* for additional information. Leveraging internal resources for a portion of future EUP work helps ensure continuity of program knowledge, effective allocation of resources across EUP and non-EUP obligations, and sustained accountability for safety, schedule, and performance outcomes.

[b]Unit Cost Basis

The baseline unit costs shown below reflect actual costs by resource group and are used as the starting point from which escalation rates and improvements are applied to derive the forecasted 2028 - 2037 EUP Unit Cost Targets. The actual unit costs shown below reflect varying levels of project complexity between resource types, which may not be indicative of the future mix of project complexity assigned to each resource group.

Resource	Unit Cost	Basis
External - Lump Sum	$2.92	2025 Actuals
Internal	$3.45	2023 - 2025 Average Actuals
External - Unit Pricing	$3.10	2023 - 2025 Average Actuals

[c]Escalated

Using the Unit Cost Basis, yearly increases in unit costs are calculated using the escalation rates below for years 2026 through 2037.

Resource	Escalation Rate Used	Escalation Rate Source
External - Lump Sum	Composite	S&P Q1 2026[1]
External - Unit Pricing		
Internal	Internal Labor	Aligned with internal labor escalation expectations
	Non-Labor	S&P Q1 2026[1]

[1] *© 2026 S&P Global Market Intelligence (and its affiliates, as applicable) (individually and collectively, "S&P"). Year	Internal Labor Escalation Rate	Non-Labor Escalation Rate	Composite Escalation Rate
2026	5.00%	4.51%	4.51%
2027	5.00%	3.70%	3.70%
2028	5.00%	2.90%	2.90%
2029	3.75%	2.37%	2.37%
2030	3.75%	2.02%	2.02%
2031	3.75%	1.99%	1.99%
2032	3.75%	2.06%	2.06%
2033	3.75%	2.13%	2.13%
2034	3.75%	2.16%	2.16%
2035	3.75%	2.16%	2.16%
2036	3.75%	2.18%	2.18%
2037	3.75%	2.18%	2.18%

[d]Unescalated

Annual unit cost values between 2028 and 2037 are presented unescalated, in 2028 dollars. Unescalated unit costs are expected to decrease by 5% from 2028 to 2037 as sourcing strategies and work execution strategies to reduce program costs described PG&E's EUP Chapter 5, Section 3.c are implemented. Additionally, unit cost reductions are also assumed in 2027 and 2028 prior to the start of the EUP period.

[e]Internal Unit Cost

Comprised of "Labor" (60.36%) and "Non-Labor" (39.64%) components; each component's escalation rate is calculated separately (where applicable).

OVERALL UTILITY RISK (OUR) TOY PROBLEM

Workpaper 031
Pacific Gas and Electric Company
Electrical Undergrounding Program
OUR Escalation Toy Problem

OUR Climate Escalation Toy Problem Results

Description: This workpaper illustrates how Overall Utility Risk (OUR) values change over the EUP planning period when both inflation and climate-driven risk escalation are incorporated. The Baseline Risk section provides the 2025 starting risk values. The Escalation Factors section shows the annual factors applied to reflect projected changes in inflation, wildfire risk, PSPS risk, and EPSS risk over time. The Escalated & Inflated Values section applies these factors to calculate annualized risk values and compares the resulting climate-adjusted OUR against a static, non-escalated baseline. The difference between the two represents the incremental increase in OUR attributable to inflation and evolving climate risk conditions throughout the EUP period.

	Inflation Rate	2.28%

Baseline Risk Values (in 2025 Values) ($M)	**Scenario**	**Low**	**Medium**	**High**
	Wildfire Risk	$1.00	$2.00	$4.00
	PSPS Risk	$0.07	$2.82	$6.51
	EPSS Risk	$0.02	$3.78	$16.08

Escalation Factors	**Year**	**2025**	**2028**	**2029**	**2030**	**2031**	**2032**	**2033**	**2034**	**2035**	**2036**	**2037**

ELECTRICAL UNDERGROUNDING PLAN

ATTACHMENT C

GLOSSARY OF TERMS

PACIFIC GAS AND ELECTRIC COMPANY
ELECTRICAL UNDERGROUNDING PLAN
ATTACHMENT C
GLOSSARY OF TERMS

The purpose of this Glossary is to define key terms and acronyms used throughout the Electrical Undergrounding Plan (EUP) and promote clarity and consistent interpretation.

The Glossary identifies terms with definitions from the Energy Safety EUP Guidelines , as well as terms that PG&E has adapted for use in this EUP. Definitions reproduced from Appendix A of the EUP Guidelines without modification are denoted by the following symbol at the end of the definition:**(ES)**.

TERMS

Aggregate Risk Analysis

The method for summing or aggregating risk metrics at the portfolio and system levels.

Alternative Mitigation

A mitigation strategy, other than Undergrounding, used to reduce the consequence or likelihood of wildfires and Outage Program Events on a particular Circuit Segment.**(ES)**

Backcasting

Recalculating prior results using updated inputs to enable consistent comparisons across model versions.

Backtesting

Retrospective comparison of outputs from different risk model versions to assess the impact of model changes.

Baseline

The expected risk and reliability profile of the Large Electrical Corporation's existing distribution system assuming that no Undergrounding Projects from the EUP program are constructed during the asset life cycle. The Baseline includes all previously approved Undergrounding Projects, system-hardening projects, and similar mitigation activities.(ES)

PG&E applies this definition to mean the “as is” system state before application of any EUP mitigation alternatives. This scenario incorporates EPSS and PSPS as operational mitigations for wildfire risk on the existing overhead system.

Benefit-Cost Ratio (BCR)

The ratio of the present value of lifetime benefits to the present value of lifetime costs for a mitigation. Consistent with Commission terminology, references to “BCR” are synonymous with the term “Cost-Benefit Ratio (CBR)” used in certain Commission guidance documents. See Resolution SPD-37, p. 2 n.3.

Bow Tie Model

A standardized, PG&E Company-wide model used to quantify enterprise risks in alignment with the CPUC’s Risk-Based Decision-Making Framework (RDF). Also referred to as the Enterprise Bow Tie Model.

Circuit Segment

An isolatable circuit segment.(ES)

Committed Miles

Undergrounding miles from scoped projects planned for completion in a specified year to meet annual targets.

Confirmed Project

An Undergrounding Project that has completed Screen 3 (Project Risk Analysis).(ES)

Confirmed Project Polygon

A spatial boundary generated at the beginning of Screen 3 that encompasses the entire Eligible Circuit Segment on which the Undergrounding Project is defined, except any sections already contained in another Confirmed Project Polygon.(ES)

Core Capabilities

The required use-cases that the Large Electrical Corporation’s Risk Modeling Methodology must be able to achieve in order to make quantitative arguments about the risk reduction of Undergrounding and Alternative Mitigations.(ES)

Cost Efficiency

The extent to which an activity delivers value, measured as benefits relative to costs.

Critical Facilities

Facilities and infrastructure that are essential to public safety and require additional assistance and advance planning to ensure resiliency during Public Safety Power Shutoff (PSPS) events.

Cumulative Risk Reduction

Total aggregated reduction in modeled risk over a defined time horizon.

Downed Conductor Detection (DCD)

A component of PG&E's Enhanced Powerline Safety Settings (EPSS) that adds an additional protection element to address fault types not fully mitigated through the EPSS Program. DCD does this by enhancing the ability to quickly detect and de-energize low and very low initial current (high-impedance) line-to-ground faults before an ignition can occur.

Eligible Circuit Segment

A Circuit Segment that falls within the risk score values that will be used to identify high risk Circuit Segments that are eligible for the 10-Year Electrical Undergrounding Program.(ES)

Enhanced Powerline Safety Settings (EPSS)

Protective settings that reduce Ignition Risk by rapidly de-energizing lines experiencing faults.

Feedback Loop

The Feedback Loop is used by PG&E for decision-support and as an evaluation process/tool used to analyze mitigation options for a Circuit Segment and generate benefit-cost and risk-reduction outcomes.

Fire Rebuild Area

An area with four or more spans of electric distribution infrastructure damaged by a fire that requires the electrical distribution facilities to be reconstructed or repaired.

See also Wildfire Rebuild Areas.

Fire Rebuild Projects

Reconstruction or repair of a Circuit Segment located in a Fire Rebuild Area.

High Fire Threat District (HFTD)

Areas of the state designated by the CPUC as having elevated wildfire risk, where each Electrical Corporation must take additional action to mitigate wildfire risk pursuant to Decision 17-01-009 or its successor.(ES)

High Fire Risk Area (HFRA)

Utility-identified area considered high risk for wildfire.

High Frequency Outage Program Project-Level Standard

The minimum decrease in Outage Program Likelihood as measured through formal calculations of the Key Decision-Making Metrics that any Undergrounding Project considered under the High Frequency Outage Program must achieve to meet the required substantial increase in electrical reliability achieved by reducing the use of Public Safety Power Shutoffs, Enhanced Powerline Safety Settings, deenergization events, and any other outage programs.(ES)

High Frequency Outage Program Threshold

The measure of likelihood above which is considered to have a significantly high likelihood of frequent or prolonged disruption of service to customers. This threshold must measure both likelihood of an Outage Program Event and its anticipated length. This threshold must represent less than 1 percent of Circuit Segments in the entire system by mile and no more than 10 percent of Outage Program Likelihood by score.(ES)

High-Risk Threshold

The Overall Utility Risk level above which a Circuit Segment is considered eligible for examination for expedited undergrounding.(ES)

Hybrid Project

A project combining undergrounding with other mitigation types on the same Circuit Segment.

Ignition Consequence

The total anticipated adverse effects from a wildfire on each community it reaches. This metric considers wildfire hazard intensity, wildfire exposure potential, and the inherent wildfire vulnerabilities of communities at risk.(ES)

PG&E applies the definition in Progress Report Table C.2 and in Chapter 7, Section E as follows: Ignition Consequence represents the mean expected damages conditional on an ignition occurring on a given circuit segment. It is calculated by dividing the monetized Ignition Risk by the Ignition Likelihood (i.e., the annual expected number of ignitions).

Ignition Likelihood

The likelihood of an ignition at a given location given a probabilistic set of environmental conditions. This is an unweighted and unscaled calculation.(ES)

PG&E applies the definition in Progress Report Table C.2 and in Chapter 7, Section E as follows: Ignition Likelihood, also known as the Probability of Ignition, is aggregated for a Circuit Segment from the suite of distribution asset and contact from object event probability models. The event probability models predict the likelihood of an ignition for an asset or location over the length of one fire season. Ignition Likelihood is represented in ignitions per year.

Ignition Risk

The measure of impacts from wildfire at a given location. This metric is the product of two factors: (1) the likelihood a wildfire will occur, and (2) the potential consequences of a wildfire originating from that location.(ES) (See also Wildfire Risk; PG&E uses these terms interchangeably).

PG&E applies the definition in Progress Report Table C.2 and in Chapter 7, Section E as follows: Ignition risks are Circuit Segment relative risk values based on the outputs of the WDRM. Ignition Risk is the product of the Probability of Ignition for an asset or location and the Wildfire Consequence at that location. The relative WDRM risk values are then calibrated against the absolute value of PG&E's Enterprise Risk Bow Tie for distribution Wildfire Risk. Ignition Risk is represented as a dollar value.

Ignition Tail Risk Threshold

The measure of consequence above which a Circuit Segment is considered to have significant potential for catastrophic wildfire, such that it merits special consideration. This threshold must represent less than 1 percent of Circuit Segments in the entire system by mile and no more than 10 percent of the wildfire consequence by score.(ES)

Ignition-Weighted Consequence

A consequence metric weighted by Ignition Likelihood to emphasize higher-risk locations.

In-Area Circuit Segment

A Circuit Segment located within the Large Electrical Corporation's service territory that is located in a Tier 2 or 3 High Fire-Threat District or a Wildfire Rebuild Area.(ES)

Ineligible Circuit Segment

A Circuit Segment that does not meet any Project-Level Thresholds and is removed from further evaluation.

Instantaneous Risk Reduction

The reduction in modeled risk at a specific point in time relative to baseline.

Interruption Cost Estimate (ICE) Calculator

A customer survey–based model developed by Lawrence Berkeley National Laboratory (LBNL) that estimates the economic impacts of power outages on customers based on outage duration, timing, and customer characteristics.

JavaScript Object Notation (JSON) Data Submissions

A data file type designed to track unstructured data that would not be appropriate for a spreadsheet format.(ES)

Key Decision-Making Metrics (KDMMs)

The key decision-making metrics developed pursuant to Section 2.7.3 of the EUP Guidelines.(ES)

Line Elimination Incentive Program (LEIP)

LEIP is a system hardening and wildfire risk reduction program through which PG&E provides financial incentives to property owners who voluntarily agree to permanently discontinue electric service, enabling the removal of overhead distribution facilities in High Fire Threat Districts and High Fire Risk Areas.

Line Removal Program

A PG&E system hardening program that eliminates overhead lines using remote grids, incentives, and land acquisition.

Mitigated Circuit Segment Standards

The Project-Level risk scores that an Eligible Circuit Segment must reach to be considered sufficiently mitigated under the terms of the EUP. These standards consist of the High-Risk Project-Level Standard, the Ignition Tail Risk Project-Level Standard, and the High Frequency Outage Program Project-Level Standard.(ES)

Model Risk Landscape (MRL)

The model risk landscape defined for the EUP pursuant to Section 2.7.4 of the EUP Guidelines.(ES)

Non-Cumulative

A metric that can only be expressed at a single point in time.

Non-EUP Project

A distribution undergrounding or other system-hardening project in Tier 2 or 3 High Fire-Threat District that is funded or in the Project Planning and Construction Phases that is not included in the 10-Year EUP.(ES)

Non-Ratepayer Funding

External funding sources used to offset Project costs.

Non-Undergrounding Subproject

A Subproject that uses an alternative system hardening mitigation other than undergrounding. Any resulting risk reduction is not counted toward EUP objectives.

Operations and Maintenance (O&M) Costs

Expected lifetime costs to operate and maintain electric utility distribution assets.

Outage Program

An Outage Program is: (i) any program that interrupts electrical service for the purpose of mitigating or avoiding the risk of causing a wildfire including Public Safety Power Shutoff (PSPS) programs, fast trip settings (including enhanced powerline safety settings, Fast Curve Settings, and Sensitive Relay Profile) and similar programs, and (ii) any program that could result in a deenergization event. Outage Programs exclude maintenance outages and other outages not related to reducing wildfire risk.(ES)

Outage Program Consequence

The total anticipated adverse effects from an Outage Program for a community. This considers the Outage Program exposure potential and inherent Outage Program vulnerabilities of communities at risk.(ES)

PG&E applies the definition in Progress Report Table C.2 and in Chapter 7, Section E as follows: The quantified the impact of an outage caused by an Outage Program on a Circuit Segment in dollars per outage minute and is used

to estimate the customer impact in terms of the Value of Service (VoS) lost for the count and type of customers impacted.

Outage Program Likelihood

The likelihood of a Large Electrical Corporation utilizing an Outage Program given a probabilistic set of environmental conditions.(ES)

PG&E applies the definition in Progress Report Table C.2 and in Chapter 7, Section E as follows: The expected number of outage minutes per year caused by an Outage Program on a Circuit Segment. It is calculated by summing the EPSS Likelihood and PSPS Likelihood.

Outage Program Risk

The measure of reliability impacts from Outage Programs at a given location. This metric is the product of two factors: (1) the likelihood an Outage Program Event will be required due to environmental conditions exceeding design conditions; and (2) the potential consequences of the Outage Program for affected customers, considering exposure potential and vulnerability. This is an unweighted and unscaled calculation.(ES)

PG&E applies the definition in Progress Report Table C.2 and in Chapter 7, Section E as follows: The summation of EPSS Risk and PSPS Risk, representing the total monetized impact of outages caused by an Outage Program and is used to calculate the Overall Utility Risk.

Outage Program Risk Model (OPRM)

The model used to estimate reliability risk from Outage Programs such as PSPS and EPSS.

Overall Utility Risk (OUR)

The combined measure of Ignition Risk and Outage Program Risk that measures the total risk of wildfires and Outage Program Events related to wildfire risks. This is computed as the inner product of the likelihoods of adverse events and their consequences. This is an unweighted and unscaled calculation.(ES)

PG&E applies the definition in Progress Report Table C.2 and in Chapter 7, Section E as follows: Overall Utility Risk is the combination of Ignition Risk and Outage Program Risk, along with considerations for climate change and

escalation. This is represented as a dollar value and is an unscaled and unweighted value.

Overhead System Hardening

Upgrades to overhead infrastructure to reduce wildfire and reliability risk, including installing stronger, more resistant poles and replacing bare powerlines with covered conductor.

Plan Mitigation Objective (PMO)

The amount of change in risk (wildfire and reliability) that is necessary to meet the substantiality requirements of section 8388.5(d)(2).(ES)

PG&E uses the term PMO as the amount of Overall Utility Risk targeted to be reduced for each primary overhead mile removed, applied across the EUP portfolio to drive consistent performance as the EUP progresses.

Plan Tracking Objectives (PTO)

Forward-looking, quantifiable measurements and objectives, measured at the Portfolio-Level and System-Level, used to assess progress toward the Plan Mitigation Objective.(ES)

Plant Maintenance (PM) Order

A unique identifier representing a work order in PG&E's internal tracking system used to plan, execute, track, and close maintenance or construction work on utility assets.

Portfolio

The set of all Confirmed Projects at Screen 3 or later. A portfolio is a unique list of Confirmed Projects, and adding or removing Confirmed Projects from the list constitutes an update to the Portfolio and must be indicated with a new portfolio ID.(ES)

Portfolio-Level

A measurement that accumulates information from every Circuit Segment on each Circuit which has one or more Confirmed Projects as well as the effects of Confirmed Projects on the overall Circuit into a single number.(ES)

Portfolio-Level Metrics

Metrics aggregating impacts across multiple projects or Circuit Segments.

Portfolio-Level Risk Reduction

Total reduction in risk achieved across the EUP portfolio.

Portfolio-Level Standards

The Ignition Risk Decrease Standard and the Reliability Increase Standard.(ES)

Primary Overhead Mile Removed

A unit representing one mile of overhead line removed and placed underground.

Prioritized Project

An Undergrounding Project that has passed Screen 4 (Prioritization and Finalization).(ES)

Project

A Circuit Segment with planned or in progress Wildfire System Hardening work.

Project Acceptance Framework

The multi-step process, described in Section 2.4 of the EUP Guidelines, that the Large Electrical Corporation will use to create the list of Undergrounding Projects pursuant to Section 8388.5(c)(2), to select Undergrounding Projects for construction, and to maintain and update the Circuit Segment Information Lists throughout the EUP 10-year period.(ES)

Project as Scoped

The full evaluated project scope, including all mitigation components.

Project Management Template

A standardized tool for tracking project schedule, milestones, and progress.

Project-Level

A measurement that accumulates risk from all of the equipment on a single Circuit Segment into a single number.(ES)

Project-Level Standards

The High-Risk Project-Level Standard, the High Frequency Outage Program Project-Level Standard, and the Tail Risk Project-Level Standard.(ES)

Project-Level Thresholds

The High-Risk Threshold, Ignition Tail Risk Threshold, and High Frequency Outage Program Threshold.(ES)

Pro-Rata Risk Allocation

Allocation of risk proportional to segment length.

Public Safety Power Shutoff (PSPS)

A PG&E Outage Program that proactively de-energizes powerlines during high wildfire risk conditions.

Reliability Risk

Risk associated with power outages and service interruptions.

Remote Grid

A standalone energy system used to replace overhead lines and enable line removal.

Reserve Miles

Additional planned Undergrounding Project miles that can be advanced if necessary.

Risk Density

Risk density represents the concentration of risk within a given unit of infrastructure, typically expressed as risk per mile. While total risk reflects overall exposure, risk density helps identify where mitigation investments can achieve the greatest risk reduction per mile treated. PG&E uses risk density to target system hardening resources to the portions of the system where they can most effectively reduce risk.

Risk Model Change Factor for Ignition Risk

An adjustment input to the Risk Model Impact Factor that represents the observed variance across Ignition Risk models (e.g., WDRM v3 (previous version of the wildfire risk model) vs. WDRM v4 (current version of the wildfire risk model).

Risk Model Change Factor for Outage Risk

An adjustment input to the Risk Model Impact Factor that represents the observed variance in Outage Risk models (e.g., Interruption Cost Estimate (ICE) 1.0 vs. ICE 2.0 value of service).

Risk Model Impact Factor

An adjustment factor, derived from the Risk Model Change Factors for Ignition Risk and Outage Risk, that quantifies the overall impact of risk model updates on Overall Utility Risk. The Risk Model Impact Factor is applied to key performance metrics, including the Plan Mitigation Objective and Plan Tracking Objective, to account for changes in modeled risk resulting from updates to the Ignition Risk and Outage Program Risk Models. This adjustment helps maintain the consistency and comparability of risk reduction metrics and performance results over time.

Risk Reduced per Mile Installed

Monetized risk reduction achieved per mile of mitigation installed.

Risk Reduced per Mile of Overhead Removed

Monetized risk reduction achieved per mile of primary overhead electric facilities removed.

Risk Reporting Unit (RRU)

A standardized unit used for reporting modeled risk.

Defined in CPUC Resolution SPD-37 as: A CPUC-jurisdictional effort within Electric Operations or Gas Operations that simultaneously removes or mitigates the risk associated with a group of contiguous assets or systems that exhibit high levels of risk. The RRU must include common elements that must include, but are not limited to Consequence Attributes, Risk level, line-item costs, benefit-cost ratios (CBRs), work units, and time. The RRU can be aggregated along several dimensions based on unique identifiers that include, but are not limited to, hierarchy, scenario, version, risk event, tranche, and mitigation types.

Short Circuit Segment

Circuit Segments that are less than one mile in length.

Subproject

A delimited portion of work on a Confirmed Project. A Subproject must have a uniform set of mitigations applied to the entire Subproject. If a project does not have a uniform set of mitigations, it must be divided into more Subprojects.(ES)

System-Level

A measurement that accumulates information from the entire electrical distribution system into a single number.(ES)

Undergrounding Program

PG&E's program to relocate overhead lines underground to reduce Wildfire Risk and Outage Program Risk.

Undergrounding Project

An Eligible Circuit Segment that has completed Screen 2, including the CPUC Data Appendix 1 information completed.(ES)

Undergrounding Subproject

A Subproject that is comprised of only Undergrounding activities, including the Undergrounding Support Work necessary to complete the Undergrounding Subproject.(ES)

Wildfire Benefit Cost Analysis (WBCA)

A PG&E model used to evaluate costs and benefits of mitigation options over asset life.

Wildfire Distribution Risk Model (WDRM)

The PG&E model used to estimate wildfire risk at the Circuit Segment level.

Wildfire Rebuild Area

A location where distribution infrastructure has been damaged by wildfire that is specifically identified by the Large Electrical Corporation in the EUP or in a Progress Report.(ES)

PG&E uses the term 'Fire Rebuild Area' to refer to areas with four or more spans of electric distribution infrastructure damaged by a fire that requires the electrical distribution facilities to be reconstructed or repaired.

Wildfire Risk

The measure of impacts from wildfire at a given location. This metric is the product of two factors: (1) the likelihood a wildfire will occur, and (2) the potential consequences of a wildfire originating from that location. (See also Ignition Risk; PG&E uses these terms interchangeably).

Workplan/EUP Workplan

The set of Projects and Subprojects planned for completion under the EUP.
